would be called a series of letters, although the letters a and b recur. But in all such cases, there is some means (in the above case, position in space) by which one *occurrence* of a given term is distinguished from another occurrence, and this will be found to mean that there is some other series (in the above case, the series of positions in a line) free from repetitions, with which our pseudo-series has a one-many correlation. Thus, in the above instance, we have a series of nine positions, which we may call

$$1,\ 2,\ 3,\ 4,\ 5,\ 6,\ 7,\ 8,\ 9,$$

which form a true series without repetitions; we have a one-many relation, that of *occupying* these positions, by means of which we distinguish occurrences of a, the first occurrence being a as the correlate of 1, the second being a as the correlate of 4. All series in which there are repetitions (which we may call pseudo-series) are thus obtained by correlation with true series, *i.e.* with series in which there is no repetition. That is to say, a pseudo-series has as its generating relation a relation of the form $S | P$, where P is a serial relation, and S is a one-many relation whose converse domain contains the field of P. Thus what we may call self-subsistent series must be series without repetitions, *i.e.* series whose generating relations are contained in diversity.

For our purposes, there is no use in distinguishing a series from its generating relation. A series is not a class, since it has a definite order, while a class has no order, but is capable of many orders (unless it contains only one term or none). The generating relation determines the order, and also the class of terms ordered, since this class is the field of the generating relation. Hence the generating relation completely determines the series, and may, for all mathematical purposes, be taken to *be* the series.

When P is transitive, we have

$$P_{po} = P \,.\, P_* = P \cup I \upharpoonright C'P.$$

Hence all the propositions of Part II, Section E become greatly simplified when applied to series.

Also, since the field of a connected relation consists of a single family, a series has one first term or none, and one last term or none.

In the case of a serial relation P, the relation P_1 (defined in $*121{\cdot}02$) becomes $P \dot{-} P^2$, *i.e.* the relation "immediately preceding." In a *discrete* series, the terms in general immediately precede other terms. A *compact* series, on the contrary, is defined as one in which there are terms between any two: in such a series, $P_1 = \dot{\Lambda}$.

It very frequently occurs that we wish to consider the relations of various series which are all contained in some one series; for example, we may wish to consider various series of real numbers, all arranged in order of magnitude. In such a case, if P is the series in which all the others are contained, and $\alpha, \beta, \gamma, \ldots$ are the fields of the contained series, the contained series themselves are $P \upharpoonright \alpha$, $P \upharpoonright \beta$, $P \upharpoonright \gamma, \ldots$. Thus when series are given as contained in a given series, they are completely determined by their fields.

In what follows, Section A deals with the elementary properties of series, including maximum and minimum points, sequent points and limits.

Section B will deal with the theory of segments and kindred topics; in this section we shall define "Dedekindian" series, and shall prove the important proposition that the series of segments of a series is always Dedekindian, *i.e.* that every class of segments has either a maximum or a limit.

Section C, which stands outside the main developments of the book, is concerned with convergence and the limits of functions and the definition of a continuous function. Its purpose is to show how these notions can be expressed, and many of their properties established, in a much more general way than is usually done, and without assuming that the arguments or values of the functions concerned are either numerical or numerically measurable.

Section D will deal with "well-ordered" series, *i.e.* series in which every class containing members of the field has a first term. The properties of

well-ordered series are many and important; most of them depend upon the fact that an extended variety of mathematical induction is possible in dealing with well-ordered series. The term "ordinal number" is confined by usage to the relation-number of a well-ordered series; ordinal numbers will also be considered in our fourth section.

Section E will deal with finite and infinite. We shall show that the distinction between "inductive" and "non-reflexive" does not arise in well-ordered series.

Section F will deal with "compact" series, *i.e.* series in which there is a term between any two, *i.e.* in which $P^2 = P$. In particular we shall consider "rational" series (*i.e.* series like the series of rationals in order of magnitude) and continuous series (*i.e.* series like the series of real numbers in order of magnitude). Our treatment of this subject will follow Cantor closely.

SECTION A

GENERAL THEORY OF SERIES

Summary of Section A.

In the present section, we shall be concerned with the properties common to all series. Such properties, for the most part, are very simple, and present no difficulties of any kind. Many of the properties of series do not require all the three characteristics by which serial relations are defined, but only one or two of these properties: we therefore begin with numbers in which, though the properties proved derive their chief importance from their applicability to series, the hypotheses are only that the relations in question have one or two of the properties of serial relations. Thence we proceed to the most elementary properties peculiar to series, and thence to the theory of minimum and maximum members of classes contained in a series, and of the successors and limits of classes. We then proceed to the correlation of a series with part of itself. The ground covered is familiar, and the difficulties encountered are less than in most previous sections.

It will be observed that where series are concerned, if α is an existent class contained in $C'P$, $p'\overleftarrow{P}``\alpha$ is correlative to $P``\alpha$ (which is $s'\overrightarrow{P}``\alpha$): $P``\alpha$ is "predecessors of some α," and $p'\overleftarrow{P}``\alpha$ is "successors of all $\alpha$'s." If $\alpha$ is an existent class contained in $C'P$, the whole of $C'P$, with the exception of the last term of $\alpha$ (if there is such a term), belongs to one or other of the classes $P``\alpha$, $p'\overleftarrow{P}``\alpha$, of which the first wholly precedes the second. The division of $C'P$ into these two classes is the Dedekind "cut" defined by $\alpha$. But when only part of $\alpha$ is contained in $C'P$, we must replace $p'\overleftarrow{P}``\alpha$ by $p'\overleftarrow{P}``(\alpha \cap C'P)$, since $p'\overleftarrow{P}``\alpha = \Lambda$ if α has any member not belonging to $C'P$. Again, if $\alpha \cap C'P = \Lambda$, we have $p'\overleftarrow{P}``(\alpha \cap C'P) = \mathrm{V}$. But what we want is the complement to $P``\alpha$, which in this case is null. Hence we must replace $p'\overleftarrow{P}``(\alpha \cap C'P)$ by $C'P \cap p'\overleftarrow{P}``(\alpha \cap C'P)$: this is $C'P$ when $P``\alpha = \Lambda$, *i.e.* when $\alpha \cap C'P = \Lambda$. In any other event it is equal to $p'\overleftarrow{P}``(\alpha \cap C'P)$. If α is contained in $C'P$ and is not null, $C'P \cap p'\overleftarrow{P}``(\alpha \cap C'P) = p'\overleftarrow{P}``\alpha$. Thus the Dedekind "cut" defined by a class α, whether or not this class is contained in whole or part in $C'P$, is always the two classes

$$P``\alpha,\ C'P \cap p'\overleftarrow{P}``(\alpha \cap C'P).$$

Throughout the elementary propositions of this section, we have been careful to avoid stronger hypotheses than are required: we have not assumed

P to be serial, if our conclusion would follow (*e.g.*) from the hypothesis that P is transitive and connected. It will be found that many properties of series depend upon the fact that, if x, y are two different terms of a series P, then $xPy . \equiv . \sim(yPx)$ (*204·3). Here the implication $xPy . \supset . \sim(yPx)$ requires that P should be asymmetrical, *i.e.* that we should have $P \dot{\wedge} \breve{P} = \dot{\Lambda}$ or $P^2 \subseteq J$. The implication $\sim(yPx) . \supset . xPy$ requires that P should be connected. Thus the hypothesis required is not that P should be serial, but that P should be connected and asymmetrical (*202·5).

Again, consider the proposition that if P is a series, $P_1 = P \dot{-} P^2$. This relation P_1 is the very useful relation "immediately preceding"; thus the above proposition is important, as is the further proposition that if P is a series, P_1 is a one-one relation. It will be remembered that (by *121) "xP_1y" means that $P(x \mapsto y)$ consists of two terms. It was shown in *121·304·305 that if P_{po} is contained in diversity, "xP_1y" implies "xPy," and is equivalent to the statement that x and y constitute the whole interval $P(x \mapsto y)$ and are not identical. Also by *121·254, $P_1 = (P_{po})_1$. It is evident that, if P_{po} is contained in diversity, and xP_1y, we cannot have xP^2y, because there is no term other than x and y in the interval $P(x \mapsto y)$, and we cannot have xPx or yPy. Hence if $P_{po} \subseteq J$, we have $P_1 \subseteq \dot{-} P^2$. Hence by what was said above (*121·305), if $P_{po} \subseteq J$, we shall have $P_1 \subseteq P \dot{-} P^2$. On the other hand, if P is transitive, we have $P \dot{-} P^2 \subseteq P_1$ (*201·61). Combining these two facts, and remembering that if P is transitive, $P = P_{po}$ (*201·18), we find that $P_1 = P \dot{-} P^2$ if P is transitive and contained in diversity. We find further (*202·7) that if P is connected, $P \dot{-} P^2$ is one-one. Hence we need the full hypothesis that P is a series in order to prove that P_1 is a one-one (*204·7). This is a good example of the way in which the various separate characteristics that make up the definition of series are relevant in proving the properties of series.

$*200$. RELATIONS CONTAINED IN DIVERSITY

Summary of $*200$.

Some of the propositions of this number are repetitions or immediate consequences of previous propositions, especially those of the propositions of $*50$ which deal with diversity. But we are chiefly concerned here with propositions which will be useful in the theory of series; this leads us to introduce propositions on $p\text{'}\overleftarrow{P}\text{''}\alpha$ and on matters connected with relation-arithmetic and other topics. It will be seen that "$P^2 \subset J$" (*i.e.* "P is asymmetrical") is an important hypothesis, as is also $P_{\text{po}} \subset J$, of the use of which we have already had examples in $*96$ and $*121$.

The following are among the most useful propositions in this number:

$*200\cdot12$. $\vdash : P \in \text{Rl}\text{'}J \,.\supset .\, C\text{'}P \sim\in 1$

This is the proposition which makes it impossible to define an ordinal number 1 which shall take its place among relation-numbers applicable to series.

$*200\cdot35$. $\vdash : P \subset J \,.\, \alpha \in 1 \,.\supset .\, P \upharpoonright \alpha = \dot{\Lambda}$

This is a consequence of $*200\cdot12$.

$*200\cdot36$. $\vdash : P^2 \subset J \,.\supset .\, P \subset J$

$*200\cdot361$. $\vdash : P^2 \subset J \,.\supset .\, \overrightarrow{P}\text{'}x \cap (\iota\text{'}x \cup \overleftarrow{P}\text{'}x) = \Lambda \,.\, \overleftarrow{P}\text{'}x \cap (\overrightarrow{P}\text{'}x \cup \iota\text{'}x) = \Lambda$

I.e. if $P^2 \subset J$, no term precedes itself or any of its predecessors, and no term succeeds itself or any of its successors.

$*200\cdot38$. $\vdash : P_{\text{po}} \subset J \,.\supset .\, P_{\text{po}} = P_* \dot{\cap} J$

$*200\cdot39$. $\vdash : P_{\text{po}} \subset J \,.\, x \in C\text{'}P \,.\supset .\, \overrightarrow{P_*}\text{'}x \cap \overleftarrow{P_*}\text{'}x = \iota\text{'}x$

We then have a collection of propositions concerned with relation-arithmetic.

$*200\cdot211$. $\vdash : P \subset J \,.\, P \,\text{smor}\, Q \,.\supset .\, Q \subset J$

I.e. the property of being contained in diversity is invariant for likeness-transformations;

$*200\cdot4$. $\vdash : P \dagger Q \in \text{Rl}\text{'}J \,.\equiv .\, P, Q \in \text{Rl}\text{'}J \,.\, C\text{'}P \cap C\text{'}Q = \Lambda$

$*200\cdot41$. $\vdash : P \rightarrow\!\!\!+ x \subset J \,.\equiv .\, x \leftarrow\!\!\!+ P \subset J \,.\equiv .\, P \subset J \,.\, x \sim\in C\text{'}P$

and other such propositions.

We then have a set of propositions concerned with $p\text{'}\overrightarrow{P}\text{''}\alpha$ and $p\text{'}\overleftarrow{P}\text{''}\alpha$. The most important are

$*200\cdot5.\quad \vdash : P \mathrel{\mathsf{G}} J . \supset . \alpha \cap p`\overrightarrow{P}``\alpha = \Lambda . \alpha \cap p`\overleftarrow{P}``\alpha = \Lambda$

$*200\cdot52.\quad \vdash : P \mathrel{\mathsf{G}} J . \supset . C`P \sim \epsilon \overrightarrow{P}``C`P$

$*200\cdot53.\quad \vdash : P^2 \mathrel{\mathsf{G}} J . \supset . P``\alpha \cap p`\overleftarrow{P}``\alpha = \Lambda . \breve{P}``\alpha \cap p`\overrightarrow{P}``\alpha = \Lambda$

I.e. if P is asymmetrical, the terms which precede part of α do not succeed the whole of α, and vice versa.

$*200\cdot11.\quad \vdash : P \epsilon \mathrm{Rl}`J . \equiv . \breve{P} \epsilon \mathrm{Rl}`J \quad [*50\cdot23]$

$*200\cdot12.\quad \vdash : P \epsilon \mathrm{Rl}`J . \supset . C`P \sim \epsilon 1$

Dem.

$\vdash . *50\cdot11 . *33\cdot17 . \supset \vdash :. \mathrm{Hp} : xPy . \mathsf{v} . yPx : \supset . y \neq x . y \epsilon C`P \qquad (1)$

$\vdash . (1) . *33\cdot132 . \quad \supset \vdash :. \mathrm{Hp} . \supset : x \epsilon C`P . \supset . (\exists y) . y \neq x . y \epsilon C`P :$

$[*52\cdot181] \qquad \supset : C`P \sim \epsilon 1 :. \supset \vdash . \mathrm{Prop}$

$*200\cdot2.\quad \vdash : T \epsilon 1 \to 1 . \supset . T;(P \dot{\cap} J) = T;P \dot{\cap} J$

Dem.

$\vdash . *150\cdot4 . \supset \vdash :. \mathrm{Hp} . \supset :$

$x \{T;(P \dot{\cap} J)\} y . \equiv . (\exists z, w) . x = T`z . y = T`w . zPw . z \neq w .$

$[*71\cdot56] \qquad \equiv . (\exists z, w) . x \neq y . x = T`z . y = T`w . zPw .$

$[*150\cdot4] \qquad \equiv . x \{T;P \dot{\cap} J\} y :. \supset \vdash . \mathrm{Prop}$

$*200\cdot21.\quad \vdash : T \epsilon \mathrm{Cls} \to 1 . P \mathrel{\mathsf{G}} J . \supset . T;P \mathrel{\mathsf{G}} J$

Dem.

$\vdash . *150\cdot1 . *50\cdot24 . \supset \vdash :. \mathrm{Hp} . \supset : x (T;P) y . \supset . (\exists z, w) . xTz . yTw . z \neq w .$

$[*71\cdot171.\mathrm{Transp}] \qquad \supset . x \neq y :. \supset \vdash . \mathrm{Prop}$

$*200\cdot211.\quad \vdash : P \mathrel{\mathsf{G}} J . P \mathrm{smor} Q . \supset . Q \mathrel{\mathsf{G}} J \quad [*200\cdot21 . *151\cdot1]$

The properties of relations are very frequently common to all relations which are like a given relation, and this applies specially to the kinds of properties with which we are most concerned. The above proposition is an illustration of this fact: it shows that the property of being contained in diversity is invariant for likeness-transformations.

$*200\cdot22.\quad \vdash : P \mathrel{\mathsf{G}} J . \equiv . \mathrm{N_0r}`P \subset \mathrm{Rl}`J . \equiv . \exists ! \mathrm{N_0r}`P \cap \mathrm{Rl}`J$

Dem. $\vdash . *155\cdot11 . *200\cdot211 . \supset \vdash : P \mathrel{\mathsf{G}} J . \supset . \mathrm{N_0r}`P \subset \mathrm{Rl}`J \qquad (1)$

$\vdash . *155\cdot12 . \qquad \supset \vdash : \mathrm{N_0r}`P \subset \mathrm{Rl}`J . \supset . P \mathrel{\mathsf{G}} J \qquad (2)$

$\vdash . *155\cdot12 . \qquad \supset \vdash : P \mathrel{\mathsf{G}} J . \supset . \exists ! \mathrm{N_0r}`P \cap \mathrm{Rl}`J \qquad (3)$

$\vdash . *155\cdot11 . *200\cdot211 . \supset \vdash : \exists ! \mathrm{N_0r}`P \cap \mathrm{Rl}`J . \supset . P \mathrel{\mathsf{G}} J \qquad (4)$

$\vdash . (1) . (2) . (3) . (4) . \supset \vdash . \mathrm{Prop}$

We have, without the need of typical definiteness,

$$\vdash : P \mathrel{\mathsf{G}} J . \supset . \mathrm{Nr}`P \subset \mathrm{Rl}`J$$

and

$$\vdash : \exists ! \mathrm{Nr}`P \cap \mathrm{Rl}`J . \supset . P \mathrel{\mathsf{G}} J,$$

both of which are immediate consequences of $*200{\cdot}211$. The converse implications, however, fail if $\text{Nr}{}^{\backprime}P$ is taken in a type in which $\text{Nr}{}^{\backprime}P = \Lambda$.

$*200{\cdot}3$. $\vdash . \dot{\Lambda} \in \text{Rl}{}^{\backprime}J$ [$*25{\cdot}12$]

$*200{\cdot}31$. $\vdash : x \neq y . \equiv . x \downarrow y \in \text{Rl}{}^{\backprime}J$ [$*55{\cdot}3$]

$*200{\cdot}32$. $\vdash : \alpha \uparrow \beta \mathrel{\mathsf{G}} J . \equiv . \alpha \cap \beta = \Lambda$ [$*50{\cdot}55$]

$*200{\cdot}33$. $\vdash : P \mathrel{\mathsf{G}} J . \supset . P \upharpoonright \alpha \mathrel{\mathsf{G}} J$ [$*35{\cdot}442$]

$*200{\cdot}34$. $\vdash : P \upharpoonright \alpha \mathrel{\mathsf{G}} J . \equiv . P \restriction \alpha \mathrel{\mathsf{G}} J . \equiv . \alpha \upharpoonleft P \mathrel{\mathsf{G}} J$ [$*50{\cdot}58$]

$*200{\cdot}35$. $\vdash : P \mathrel{\mathsf{G}} J . \alpha \in 1 . \supset . P \upharpoonright \alpha = \dot{\Lambda}$

Dem.

$\vdash . *52{\cdot}16 . \supset \vdash :. \text{Hp} . \supset : x, y \in \alpha . \supset_{x,y} . \sim (xJy) .$

[$*23{\cdot}81$] $\supset_{x,y} . \sim (xPy) :$

[$*11{\cdot}521$] $\supset : (x, y) . \sim \{x, y \in \alpha . xPy\} :. \supset \vdash . \text{Prop}$

$*200{\cdot}36$. $\vdash : P^2 \mathrel{\mathsf{G}} J . \supset . P \mathrel{\mathsf{G}} J$ [$*50{\cdot}45$]

$*200{\cdot}361$. $\vdash : P^2 \mathrel{\mathsf{G}} J . \supset . \overrightarrow{P}{}^{\backprime}x \cap (\iota{}^{\backprime}x \cup \overleftarrow{P}{}^{\backprime}x) = \Lambda . \overleftarrow{P}{}^{\backprime}x \cap (\overrightarrow{P}{}^{\backprime}x \cup \iota{}^{\backprime}x) = \Lambda$

Dem.

$\vdash\,.\,(2)\,.\,(3)\,.\,\supset \vdash\,.\,\mathrm{Prop}$

***200·51.** $\vdash : P \Subset J \,.\, \dot{\exists} ! P \,.\, \supset \,.\, p^{\backprime}\overrightarrow{P}^{\backprime\backprime}C^{\backprime}P = \Lambda \,.\, p^{\backprime}\overleftarrow{P}^{\backprime\backprime}C^{\backprime}P = \Lambda$

Dem. $\vdash \,.\, *40\cdot62 \,.\, \supset \vdash : \mathrm{Hp} \,.\, \supset \,.\, p^{\backprime}\overrightarrow{P}^{\backprime\backprime}C^{\backprime}P \subset C^{\backprime}P \,.$

$[*22\cdot621] \qquad \supset \,.\, p^{\backprime}\overrightarrow{P}^{\backprime\backprime}C^{\backprime}P = C^{\backprime}P \cap p^{\backprime}\overrightarrow{P}^{\backprime\backprime}C^{\backprime}P$

$[*200\cdot5] \qquad = \Lambda \qquad (1)$

Similarly $\vdash : \mathrm{Hp} \,.\, \supset \,.\, p^{\backprime}\overleftarrow{P}^{\backprime\backprime}C^{\backprime}P = \Lambda \qquad (2)$

$\vdash \,.\, (1) \,.\, (2) \,.\, \supset \vdash \,.\, \mathrm{Prop}$

***200·52.** $\vdash : P \Subset J \,.\, \supset \,.\, C^{\backprime}P \sim\in \overrightarrow{P}^{\backprime\backprime}C^{\backprime}P$

Dem. $\vdash \,.\, *50\cdot24 \,.\, \supset \vdash :. \mathrm{Hp} \,.\, \supset : x \in C^{\backprime}P \,.\, \supset_x \,.\, x \sim\in \overrightarrow{P}^{\backprime}x \,.$

$[*13\cdot14] \qquad \supset_x \,.\, C^{\backprime}P \neq \overrightarrow{P}^{\backprime}x :$

$[*37\cdot7.\mathrm{Transp}] \qquad \supset : C^{\backprime}P \sim\in \overrightarrow{P}^{\backprime\backprime}C^{\backprime}P :. \supset \vdash \,.\, \mathrm{Prop}$

This proposition is often used in the theory of well-ordered series.

***200·53.** $\vdash : P^2 \Subset J \,.\, \supset \,.\, P^{\backprime\backprime}\alpha \cap p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha = \Lambda \,.\, \breve{P}^{\backprime\backprime}\alpha \cap p^{\backprime}\overrightarrow{P}^{\backprime\backprime}\alpha = \Lambda$

Dem.

$\vdash \,.\, *37\cdot1 \,.\, *40\cdot53 \,.\, \supset \vdash :. x \in P^{\backprime\backprime}\alpha \cap p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha \,.\, \supset : (\exists y) \,.\, y \in \alpha \,.\, xPy : y \in \alpha \,.\, \supset_y \,.\, yPx :$

$[*10\cdot56] \qquad \supset : (\exists y) \,.\, xPy \,.\, yPx :$

$[*34\cdot5] \qquad \supset : xP^2x :$

$[*50\cdot24] \qquad \supset : \sim(P^2 \Subset J) \qquad (1)$

$\vdash \,.\, (1) \,.\, \mathrm{Transp} \,.\, \supset \vdash : \mathrm{Hp} \,.\, \supset \,.\, (x) \,.\, x \sim\in P^{\backprime\backprime}\alpha \cap p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha \qquad (2)$

Similarly $\vdash : \mathrm{Hp} \,.\, \supset \,.\, (x) \,.\, x \sim\in \breve{P}^{\backprime\backprime}\alpha \cap p^{\backprime}\overrightarrow{P}^{\backprime\backprime}\alpha \qquad (3)$

$\vdash \,.\, (2) \,.\, (3) \,.\, \supset \vdash \,.\, \mathrm{Prop}$

The above proposition is frequently used. If α is an existent class contained in $C^{\backprime}P$, $P^{\backprime\backprime}\alpha$ and $p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha$ are the two parts of the Dedekind "cut" determined by α (excluding the maximum of α, if any). The above proposition shows that these two parts are mutually exclusive.

***200·54.** $\vdash : P \Subset J \,.\, \dot{\exists} ! P \,.\, \supset \,.\, p^{\backprime}\overrightarrow{P}^{\backprime\backprime}\{C^{\backprime}P \cap p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha\} = p^{\backprime}\overrightarrow{P}^{\backprime\backprime}p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha$

Dem. $\vdash \,.\, *40\cdot62 \,.\, \supset \vdash : \exists ! \alpha \,.\, \supset \,.\, C^{\backprime}P \cap p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha = p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha \qquad (1)$

$\vdash \,.\, *40\cdot2 \,.\, \supset \vdash : \alpha = \Lambda \,.\, \supset \,.\, p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha = \mathrm{V} \,. \qquad (2)$

$[*40\cdot16] \qquad \supset \,.\, p^{\backprime}\overrightarrow{P}^{\backprime\backprime}p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha \subset p^{\backprime}\overrightarrow{P}^{\backprime\backprime}C^{\backprime}P \qquad (3)$

$\vdash \,.\, (3) \,.\, *200\cdot51 \,.\, \supset \vdash : \mathrm{Hp} \,.\, \alpha = \Lambda \,.\, \supset \,.\, p^{\backprime}\overrightarrow{P}^{\backprime\backprime}p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha = \Lambda \qquad (4)$

$\vdash \,.\, (2) \,.\, *24\cdot26 \,.\, \supset \vdash : \alpha = \Lambda \,.\, \supset \,.\, C^{\backprime}P \cap p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha = C^{\backprime}P \qquad (5)$

$\vdash \,.\, (5) \,.\, *200\cdot51 \,.\, \supset \vdash : \mathrm{Hp} . \alpha = \Lambda . \supset . p^{\backprime}\overrightarrow{P}^{\backprime\backprime}(C^{\backprime}P \cap p^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha) = \Lambda \qquad (6)$

$\vdash \,.\, (1) \,.\, (4) \,.\, (6) \,.\, \supset \vdash \,.\, \mathrm{Prop}$

This proposition is a lemma whose purpose is to avoid the necessity of introducing the hypothesis $\exists ! \alpha$ in proofs in which it is not really necessary. The first use of this proposition occurs in *206·551.

$*201$. TRANSITIVE RELATIONS

Summary of $*201$.

There are two main varieties of transitive relations, namely those that are symmetrical ($P = \breve{P}$), and those that are asymmetrical ($P \mathrel{\dot{\cap}} \breve{P} = \dot{\Lambda}$). Transitive *symmetrical* relations have the formal properties of equality; examples of such relations have occurred above, *e.g.* identity, similarity, and likeness. The propositions of the present number, however, are rather such as will be useful in connection with transitive *asymmetrical* relations, since they are intended to be applied to series.

We denote the class of transitive relations by "trans"; thus

$$\text{trans} = \hat{P}(P^2 \mathrel{\dot{\subset}} P) \quad \text{Df.}$$

Many propositions of this number are analogous to propositions whose numbers have the same decimal part in $*200$. Such are: If P is transitive, so is its converse ($*201{\cdot}11$), and so is any relation which is like P ($*201{\cdot}211$); $\dot{\Lambda}$ and $x \downarrow y$ are transitive ($*201{\cdot}3{\cdot}31$); if P is transitive, so is $P \upharpoonright\!\!\!\!\upharpoonleft \alpha$ ($*201{\cdot}33$). The propositions $*201{\cdot}4$—$\cdot 42$, which deal with the ideas of relation-arithmetic, are also analogous to $*200{\cdot}4$—$\cdot 42$.

Most of the other propositions of this number, however, have no analogues in $*200$. Among the most important of these are the following:

$*201{\cdot}14$. $\vdash : P \in \text{trans} \,.\, xPy \,.\, \supset \,.\, \overrightarrow{P}\text{‘}x \subset \overrightarrow{P}\text{‘}y$

$*201{\cdot}15$. $\vdash \,.\, R_* \in \text{trans}$

$*201{\cdot}18$. $\vdash : P^2 \mathrel{\dot{\subset}} P \,.\, \supset \,.\, P_{\text{po}} = P \,.\, P_* = P \mathrel{\dot{\cup}} I \upharpoonright C\text{‘}P$

This proposition is very important, since it effects an immense simplification in the use of all propositions involving P_{po} or P_*, when these propositions are to be applied to transitive relations. Owing to the above proposition, P_{po} drops out where transitive relations are concerned. P_*, on the other hand, remains useful: if $y \in C\text{‘}P$, "xP_*y" will mean "x precedes or is y," which, if P generates a series of which x and y are members, is equivalent to "x does not follow y."

We have a series of propositions ($*201{\cdot}5$—$\cdot 56$) on $P\text{“}\alpha$ and $p\text{‘}\overrightarrow{P}\text{“}\alpha$. The chief of these are

$*201{\cdot}5$. $\vdash : P \in \text{trans} \,.\, \supset \,.\, P\text{“}P\text{“}\alpha \subset P\text{“}\alpha$

$*201{\cdot}501$. $\vdash : P \in \text{trans} \,.\, \supset \,.\, P\text{“}\overrightarrow{P}\text{‘}x \subset \overrightarrow{P}\text{‘}x$

These two propositions express the fact that a predecessor of a predecessor is a predecessor.

$*201\cdot52$. $\vdash : P \in \text{trans} . \supset . P_*``\alpha = P``\alpha \cup (\alpha \cap C`P)$

Thus if $\alpha \subset C`P$, $P_*``\alpha$ consists of α together with the predecessors of its members.

$*201\cdot521$. $\vdash : P \in \text{trans} . x \in C`P . \supset . \overrightarrow{P_*}`x = \overrightarrow{P}`x \cup \iota`x$

$*201\cdot55$. $\vdash : P \in \text{trans} . \supset . P``(\alpha \cup P``\alpha) = P``\alpha$

We have next a set of important propositions on $P \dot{-} P^2$ and P_1. The chief are

$*201\cdot63$. $\vdash : P \in \text{trans} \cap \text{Rl}`J . \supset . P_1 = P \dot{-} P^2$

$*201\cdot65$. $\vdash :. P \in \text{trans} \cap \text{Rl}`J . \supset : P_1 = \dot{\Lambda} . \equiv . P^2 = P$

On these two propositions, see the notes appended to them below.

$*201\cdot01$. $\text{trans} = \hat{P}(P^2 \mathrel{\dot{\subset}} P)$ Df

$*201\cdot1$. $\vdash : P \in \text{trans} . \equiv . P^2 \mathrel{\dot{\subset}} P$ $[(*201\cdot01)]$

$*201\cdot11$. $\vdash : P \in \text{trans} . \equiv . \breve{P} \in \text{trans}$

Dem.

$\vdash . *201\cdot1 . *31\cdot4 . \supset \vdash : P \in \text{trans} . \equiv . \text{Cnv}`P^2 \mathrel{\dot{\subset}} \breve{P} .$

$[*34\cdot63 . *201\cdot1] \qquad \equiv . \breve{P} \in \text{trans} : \supset \vdash . \text{Prop}$

$*201\cdot12$. $\vdash :. P \in \text{trans} . \supset : P \mathrel{\dot{\subset}} J . \equiv . P^2 \mathrel{\dot{\subset}} J . \equiv . P \mathbin{\dot{\cap}} \breve{P} = \dot{\Lambda}$ $[*50\cdot47]$

In virtue of this proposition, being contained in diversity is equivalent (where transitive relations are concerned) to asymmetry. This is not in general the case with relations which are not transitive; thus *e.g.* diversity itself is contained in diversity, but is symmetrical.

$*201\cdot13$. $\vdash . \text{Rl}`I \subset \text{trans}$

Dem.

$\vdash . *34\cdot34 . \supset \vdash : R \mathrel{\dot{\subset}} I . \supset . R^2 \mathrel{\dot{\subset}} R \mid I .$

$[*50\cdot4] \qquad \supset . R^2 \mathrel{\dot{\subset}} R : \supset \vdash . \text{Prop}$

$*201\cdot14$. $\vdash : P \in \text{trans} . xPy . \supset . \overrightarrow{P}`x \subset \overrightarrow{P}`y$

Dem.

$\vdash . *201\cdot1 . \supset \vdash : \text{Hp} . zPx . \supset . zPy \qquad (1)$

$\vdash . (1) . *32\cdot18 . \supset \vdash . \text{Prop}$

The following propositions ($*201\cdot15$—$\cdot19$) are concerned with R_* and R_{po}.

$*201\cdot15$. $\vdash . R_* \in \text{trans}$ $[*90\cdot17]$

$*201\cdot16$. $\vdash . R_{po} \in \text{trans}$ $[*91\cdot56]$

This proposition is important, since it often happens that a series is given as defined by a one-one relation R, as in $*122$ for example, and in such cases R_{po} is a serial relation in our present sense. By the above proposition, R_{po}

is always transitive; by $*96{\cdot}421$, R_{po} is connected when confined to the posterity of a given term, provided $R \in \text{Cls} \to 1$; by $*96{\cdot}23$, if $R \in 1 \to \text{Cls}$ and xBR, R_{po} is contained in diversity throughout the posterity of x. Thus if R is a one-one, R_{po} confined to any family which has a beginning will be a serial relation.

***201·17.** $\vdash : P^2 \subseteq P \,.\, Q \in \text{Pot}`P \,.\, \supset .\, Q \subseteq P$

Dem. $\vdash .\, *34{\cdot}34 \,.\, \supset \vdash :.\, \text{Hp} \,.\, \supset : S \subseteq P \,.\, \supset_S .\, S \,|\, P \subseteq P$ (1)

$\vdash .\, *91{\cdot}171 \dfrac{S \subseteq P}{\phi S} .\, \supset$

$\vdash :.\, Q \in \text{Pot}`P : S \subseteq P \,.\, \supset_S .\, S \,|\, P \subseteq P : P \subseteq P : \supset .\, Q \subseteq P$ (2)

$\vdash .\, (1) \,.\, (2) \,.\, *23{\cdot}42 \,.\, \supset \vdash .\, \text{Prop}$

***201·18.** $\vdash : P^2 \subseteq P \,.\, \supset .\, P_{\text{po}} = P \,.\, P_* = P \cup I \upharpoonright C`P$

Dem. $\vdash .\, *201{\cdot}17 \,.\, *41{\cdot}151 \,.\, (*91{\cdot}05) \,.\, \supset \vdash : \text{Hp} \,.\, \supset .\, P_{\text{po}} \subseteq P$ (1)

$\vdash .\, (1) \,.\, *91{\cdot}502 \,.\quad \supset \vdash : \text{Hp} \,.\, \supset .\, P_{\text{po}} = P$ (2)

$\vdash .\, (2) \,.\, *91{\cdot}54 \,.\, \supset \vdash .\, \text{Prop}$

This proposition is important, since it simplifies all propositions concerning P_{po} and P_* in case P is transitive. The following proposition is an instance of this simplification.

***201·19.** $\vdash : P \in \text{trans} \,.\, \supset .\, P(x - y) = \overleftarrow{P}`x \cap \overrightarrow{P}`y$ [$*201{\cdot}18 \,.\, (*121{\cdot}01)$]

The following propositions ($*201{\cdot}2$—$\cdot 22$) are concerned in proving that transitiveness is unaffected by likeness-transformations, and therefore belongs to every member of a relation-number or to none.

***201·2.** $\vdash : S \in \text{Cls} \to 1 \,.\, \text{C}`Q \subset \text{C}`S \,.\, \supset .\, (S;Q)^2 = S;Q^2$

Dem. $\vdash .\, *150{\cdot}1 \,.\, \supset \vdash .\, (S;Q)^2 = S \,|\, Q \,|\, \breve{S} \,|\, S \,|\, Q \,|\, \breve{S}$ (1)

$\vdash .\, *72{\cdot}601 \,.\, \supset \vdash : \text{Hp} \,.\, \supset .\, Q \,|\, \breve{S} \,|\, S = Q$ (2)

$\vdash .\, (1) \,.\, (2) \,.\, \supset \vdash : \text{Hp} \,.\, \supset .\, (S;Q)^2 = S \,|\, Q^2 \,|\, \breve{S} : \supset \vdash .\, \text{Prop}$

***201·201.** $\vdash : S \in \text{Cls} \to 1 \,.\, \text{D}`Q \subset \text{C}`S \,.\, \supset .\, (S;Q)^2 = S;Q^2$
[Proof as in $*201{\cdot}2$]

***201·21.** $\vdash : S \in \text{Cls} \to 1 \,.\, Q \in \text{trans} \,.\, \supset .\, S;Q \in \text{trans}$

Dem. $\vdash .\, *150{\cdot}36 \,.\, *35{\cdot}452 \,.\, \supset \vdash .\, S;Q = S;Q \upharpoonright \text{C}`S$ (1)

$\vdash .\, (1) \,.\, *201{\cdot}2 \,.\quad \supset \vdash : \text{Hp} \,.\, \supset .\, (S;Q)^2 = S;(Q \upharpoonright \text{C}`S)^2 \,.$

[$*150{\cdot}31 . *201{\cdot}1$] $\supset .\, (S;Q)^2 \subseteq S;Q : \supset \vdash .\, \text{Prop}$

***201·211.** $\vdash : P \in \text{trans} \,.\, Q \,\text{smor}\, P \,.\, \supset .\, Q \in \text{trans}$ [$*201{\cdot}21 \,.\, *151{\cdot}1$]

This shows that transitiveness is a property which is unchanged by likeness-transformations. Hence

***201·212.** $\vdash : P \in \text{trans} \,.\, \supset .\, \text{Nr}`P \subset \text{trans}$ [$*201{\cdot}211$]

***201·22.** $\vdash : P \epsilon \text{trans} . \equiv . \text{N}_0\text{r}'P \subset \text{trans} . \equiv . \exists ! \text{N}_0\text{r}'P \cap \text{trans}$
[Proof as in *200·22]

***201·3.** $\vdash . \dot{\Lambda} \epsilon \text{trans}$

Dem. $\vdash . *34{\cdot}32 . \quad \supset \vdash . \dot{\Lambda}^2 = \dot{\Lambda}$ (1)

$\vdash . (1) . *23{\cdot}42 . \supset \vdash . \dot{\Lambda}^2 \mathrel{\dot\subset} \dot{\Lambda} . \supset \vdash . \text{Prop}$

***201·31.** $\vdash . x \downarrow y \epsilon \text{trans}$

Dem. $\vdash . *55{\cdot}13 . \supset \vdash : z (x \downarrow y)^2 w . \equiv . (\exists u) . z = x . u = y . u = x . w = y .$

$[*10{\cdot}35] \qquad \supset . z = x . w = y .$

$[*55{\cdot}13] \qquad \supset . z (x \downarrow y) w : \supset \vdash . \text{Prop}$

Unless $x = y$, $(x \downarrow y)^2 = \dot{\Lambda}$. A relation whose square is $\dot{\Lambda}$ is transitive, because $\dot{\Lambda}$ is contained in every relation.

***201·32.** $\vdash . \alpha \uparrow \beta \epsilon \text{trans}$

Dem. $\vdash . *35{\cdot}103 . \supset \vdash : x (\alpha \uparrow \beta)^2 z . \equiv . (\exists y) . x \epsilon \alpha . y \epsilon \beta . y \epsilon \alpha . z \epsilon \beta .$

***201·63.** $\vdash : P \epsilon \text{trans} \cap \text{Rl}`J . \supset . P_1 = P \dot{-} P^2$ [*201·62]

The above proposition is of fundamental importance. The relation P_1 (defined in *121) plays a great part in the theory of series. It is the relation "immediately preceding." Its domain consists of those terms which have immediate successors; its converse domain, of those that have immediate predecessors. In well-ordered series, $\text{D}`P_1 = \text{D}`P$, while $\text{Ɑ}`P_1$ consists of all terms (except the first) which do not belong to the first derivative (cf. *216). In any series, $\text{Ɑ}`P - \text{Ɑ}`P_1$ consists of all the terms which are limits of ascending series, and $\text{D}`P - \text{D}`P_1$ consists of all the terms which are limits of descending series.

$\vdash . *33{\cdot}151{\cdot}4 . *60{\cdot}38 . \supset$

$\vdash : \mathrm{Hp} . y \epsilon \mathrm{D}‘P - \text{Ɑ}‘P . \supset . \overleftarrow{P}‘y \epsilon 1 . y \sim\epsilon \overleftarrow{P}‘y . \overleftarrow{P}‘y = \text{Ɑ}‘P .$

[$*53{\cdot}3$] $\supset . \mathrm{E} ! \breve{P}‘y . y \neq \breve{P}‘y . \iota‘\breve{P}‘y = \text{Ɑ}‘P .$

[$*201{\cdot}66{\cdot}11 . *121{\cdot}26$] $\supset . y P_1 (\breve{P}‘y) . \iota‘\breve{P}‘y = \text{Ɑ}‘P : \supset \vdash . \mathrm{Prop}$

The above proposition is a lemma for the following.

$*201{\cdot}662$. $\vdash : P \epsilon \mathrm{trans} . \exists ! \overrightarrow{B}‘P . \exists ! \text{Ɑ}‘P - \text{Ɑ}‘P_1 . \supset . \text{Ɑ}‘P \sim\epsilon 1$

[$*201{\cdot}661$. Transp]

This proposition is first used in $*253{\cdot}521$.

*202. CONNECTED RELATIONS

Summary of *202.

A relation is said to be *connected* when either it or its converse holds between any two different members of its field, *i.e.* when, if $x, y \in C'P \,.\, x \neq y$, we have $xPy \,.\vee.\, yPx$. Thus the field of a connected relation consists of a single family, unless the relation is null, in which case it has no families. Conversely, a relation which has one family or none is connected. Connection is necessary, in addition to transitiveness and asymmetry, in order that a relation may generate a single series. If λ is a class of transitive or asymmetrical relations, $\dot{s}'\lambda$ is transitive or asymmetrical; but if λ is a class of connected relations, $\dot{s}'\lambda$ is not in general connected. Hence if λ is a class of series, $\dot{s}'\lambda$ is not one series, but many detached series. This is one reason why the arithmetical sum of a relation of relations is not defined as $\dot{s}'C'P$, but as $\dot{s}'C'P \,\dot{\cup}\, F \,;\, P$ (cf. *162), because the latter, but not in general the former, is connected when P and all the members of $C'P$ are connected (*202·42).

When P is connected, if α is any class contained in $C'P$, we have

$$C'P = P''\alpha \cup \alpha \cup (C'P \cap p'\overleftarrow{P}''\alpha),$$

and there is at most one member of α belonging neither to $P''\alpha$ nor to $C'P \cap p'\overleftarrow{P}''\alpha$. This member of α, if it exists, is the maximum of α. If, further, $P^2 \subset J$ (*i.e.* if P is asymmetrical), $(P''\alpha \cup \alpha) \cap (C'P \cap p'\overleftarrow{P}''\alpha) = \Lambda$. Thus when P is both connected and asymmetrical, $P''\alpha \cup \alpha$ and $C'P \cap p'\overleftarrow{P}''\alpha$ are each other's complements, and the two together constitute the Dedekind cut defined by α, $P''\alpha \cup \alpha$ being all the terms that do not follow the whole of α, and $C'P \cap p'\overleftarrow{P}''\alpha$ being all the terms that do follow the whole of α.

More generally, if α is any class, not necessarily contained in $C'P$, then when P is connected, we have

$$C'P - p'\overleftarrow{P}''(\alpha \cap C'P) \subset P''\alpha \cup (\alpha \cap C'P),$$

and when P is asymmetrical, we have

$$P''\alpha \cup (\alpha \cap C'P) \subset C'P - p'\overleftarrow{P}''\alpha.$$

Thus when both conditions are fulfilled, we have (*202·503)

$$C'P - p'\overleftarrow{P}''(\alpha \cap C'P) = P''\alpha \cup (\alpha \cap C'P).$$

The above inclusions and the consequent equality will be constantly required throughout what follows. The division of $C'P$ into the two mutually exclusive parts

$$P''\alpha \cup (\alpha \cap C'P) \text{ and } C'P \cap p'\overleftarrow{P}''(\alpha \cap C'P)$$

is the Dedekind "cut" defined by the class α. If $\alpha \subset C\text{‘}P$, the two parts become, as above mentioned,

$$P\text{“}\alpha \cup \alpha \text{ and } C\text{‘}P \cap p\text{‘}\overleftarrow{P}\text{“}\alpha.$$

If, further, α is not null, they become

$$P\text{“}\alpha \cup \alpha \text{ and } p\text{‘}\overleftarrow{P}\text{“}\alpha.$$

If α is contained in $C\text{‘}P$ and contains all its own predecessors, they become

$$\alpha \text{ and } C\text{‘}P \cap p\text{‘}\overleftarrow{P}\text{“}\alpha.$$

In this simplified form, Dedekind "cuts" will be considered later (*211).

We take as our definition

$$\text{connex} = \hat{P}\{x \in C\text{‘}P \,.\supset_x .\, \overleftrightarrow{P}\text{‘}x = C\text{‘}P\} \quad \text{Df.}$$

Some of the propositions of the present number are analogues of propositions in *200 and *201. Such are: If P is connected, so is $\breve{P}$ (*202·11); if P is connected, so is any similar relation (*202·211); $\dot{\Lambda}$ and $x \downarrow y$ are connected (*202·3·31); if P is connected, so is $P \upharpoonright \alpha$ (*202·33); and various propositions connected with relation-arithmetic (*202·4—·42). The majority of the propositions of this number, however, deal with properties peculiar to connexity. Among the most important of these are:

*202·101. $\vdash :. P \in \text{connex} \,.\equiv :\, x \in C\text{‘}P \,.\supset_x .\, \overrightarrow{P}\text{‘}x \cup \iota\text{‘}x \cup \overleftarrow{P}\text{‘}x = C\text{‘}P$

*202·103. $\vdash :: P \in \text{connex} \,.\equiv :.\, x, y \in C\text{‘}P \,.\supset_{x,y} :\, xPy \,.\vee.\, x = y \,.\vee.\, yPx$

These are merely alternative forms of the definition.

*202·13. $\vdash : R_* \in \text{connex} \,.\equiv.\, R_{\text{po}} \in \text{connex}$

*202·5. $\vdash :. P \in \text{connex} \,.\, P^2 \mathrel{\text{ɢ}} J \,.\, x, y \in C\text{‘}P \,.\supset :\, x \neq y \,.\, \sim(xPy) \,.\equiv.\, yPx$

*202·501. $\vdash : P \in \text{connex} \,.\supset.\, C\text{‘}P - \alpha - P\text{“}\alpha \subset p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P)$

*202·503. $\vdash : P \in \text{connex} \,.\, P^2 \mathrel{\text{ɢ}} J \,.\supset.\, C\text{‘}P - p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P) = (\alpha \cap C\text{‘}P) \cup P\text{“}\alpha$

*202·505. $\vdash : P \in \text{connex} \,.\supset.\, C\text{‘}P = P\text{“}\alpha \cup (\alpha \cap C\text{‘}P) \cup \{C\text{‘}P \cap p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P)\}$

*202·52. $\vdash : P \in \text{connex} \,.\supset.\, \overrightarrow{B}\text{‘}P, \overrightarrow{B}\text{‘}\breve{P} \in 0 \cup 1$

*202·524. $\vdash : P \in \text{connex} \,.\, \exists ! \overrightarrow{B}\text{‘}P \,.\supset.\, \text{Ɑ}\text{‘}P = \overleftarrow{P}\text{‘}B\text{‘}P$

*202·55. $\vdash : P \upharpoonright \alpha \in \text{connex} \,.\, \alpha \subset C\text{‘}P \,.\, \alpha \sim\in 1 \,.\supset.\, C\text{‘}P \upharpoonright \alpha = \alpha$

In virtue of this proposition (and others) if P is a series and α is a class (not a unit class) contained in $C\text{‘}P$, $P \upharpoonright \alpha$ is the generating relation of the series consisting of the class α in the order which it has in the series P.

*202·7. $\vdash : P \in \text{connex} \,.\supset.\, P \dot{-} P^2 \in 1 \to 1$

This proposition is to be taken in connection with *201·63. The two together show that when P is a series, P_1 is one-one.

The following propositions (∗202·511—·524) are concerned with $\overrightarrow{B}\text{‘}P$. ∗202·52 shows that if $P \in$ connex, P cannot have more than one first term or more than one last term, and ∗202·523 shows that this still holds if only P_* is connected. ∗202·511 shows that if P is a connected relation which has a first term, then if α is any class, there are predecessors of the whole of $\alpha \cap C\text{‘}P$ when and only when $B\text{‘}P$ is such a predecessor, and when and only

when $B`P \sim\epsilon\, \alpha$. *202·524 shows that if $P$ is connected and has a first term, $\text{Ɑ}`P$ consists of the successors of the first term. These propositions are much used.

$\vdash \,.\, (2) \,.\, (3) \,.\, *202\cdot104 \,.\, \supset \vdash :. \text{Hp} \,.\, \supset : x, y \,\epsilon\, C\text{‘}Q \,.\, xPy \,.\, \supset \,.\, xQy :$

$[*36\cdot13] \quad \supset : x\,(P \upharpoonright C\text{‘}Q)\,y \,.\, \supset \,.\, xQy \quad (4)$

$\vdash \,.\, (1) \,.\, (4) \,.\, \supset \vdash \,.\, \text{Prop}$

This proposition is important in series. If P and Q are serial relations, and $Q \mathrel{\subseteq} P$, they verify the above hypothesis; hence if Q is a series contained in a given series P, Q is simply P with its field limited. Thus series contained in a given series are completely determined by their fields.

***202·54.** $\vdash : P \upharpoonright \alpha \,\epsilon\, \text{connex} \,.\, \alpha \cap C\text{‘}P \sim\epsilon\, 1 \,.\, \supset \,.\, C\text{‘}P \upharpoonright \alpha = \alpha \cap C\text{‘}P$

The above proposition shows that if Q is connected, and any class β is picked out of $C`Q$, and P is similar to Q, then Q arranges β in an order which is similar to that in which P arranges the correlates of β.

$*204$. ELEMENTARY PROPERTIES OF SERIES

Summary of $*204$.

In this number we give the definition and a few of the simpler properties of series. Most of the propositions of this number result immediately from those of $*200$, $*201$, and $*202$. Our definition is

$$\text{Ser} = \text{Rl}`J \cap \text{trans} \cap \text{connex} \quad \text{Df.}$$

We have

$*204\cdot16$. $\vdash : P \epsilon \text{Ser} . \equiv . P \epsilon \text{connex} . P^2 \mathrel{\subset\!\!\!\cdot} J . P^3 \mathrel{\subset\!\!\!\cdot} J . \equiv . P \epsilon \text{connex} . P_{\text{po}} \mathrel{\subset\!\!\!\cdot} J$

either of which might have been taken as the definition.

After a few propositions giving other possible forms of the definition of series, we proceed to a set of propositions which follow immediately from those of $*200$, $*201$, and $*202$. Such are

$*204\cdot2$. $\vdash : P \epsilon \text{Ser} . \equiv . \breve{P} \epsilon \text{Ser}$

$*204\cdot21$. $\vdash : P \epsilon \text{Ser} . P \,\text{smor}\, Q . \supset . Q \epsilon \text{Ser}$

$*204\cdot24$. $\vdash . \dot{\Lambda} \epsilon \text{Ser}$

$*204\cdot25$. $\vdash : x \neq y . \equiv . x \downarrow y \epsilon \text{Ser}$

Another important proposition on couples is

$*204\cdot272$. $\vdash :. P \epsilon \text{Ser} . \supset : \text{D}`P \epsilon 1 . \equiv . P \epsilon 2_r . \equiv . \text{G}`P \epsilon 1$

so that couples are the only series having unit classes for their domains or converse domains.

We then proceed to a set of propositions on $\overrightarrow{P}`x$. We have

$*204\cdot33$. $\vdash :. P \epsilon \text{Ser} . x, y \epsilon C`P . \supset : x \neq y . \overrightarrow{P}`y \subset \overrightarrow{P}`x . \equiv . yPx$

Also, if $P \epsilon \text{Ser}$, $\overrightarrow{P} \upharpoonright C`P$ is a one-one and $\overrightarrow{P} ; P$ smor P ($*204\cdot34\cdot35$).

We then have some propositions ($*204\cdot4$—$\cdot44$) on relations with limited fields. The most important of these are

$*204\cdot4$. $\vdash : P \epsilon \text{Ser} . \supset . P \upharpoonright \alpha \epsilon \text{Ser}$

$*204\cdot41$. $\vdash : P, Q \epsilon \text{Ser} . Q \mathrel{\subset\!\!\!\cdot} P . \supset . Q = P \upharpoonright C`Q$

This proposition is important, since it shows that any series contained in a given series is wholly determined when its field is given.

We have next a number of propositions ($*204\cdot45$—$\cdot59$) applying relation-arithmetic to series. The first set of these ($*204\cdot45$—$\cdot483$) are concerned with the proof that if a "cut" is made in a series, the series is the sum of the two parts into which the cut divides it, where the sum is taken in the sense of $*160$ or $*161$, according as one part of the cut does not or does

consist of a single term. Most of these propositions do not require the full hypothesis that P is a series, but only some part of it. Thus we have for instance

$*204{\cdot}46.\quad \vdash : P \epsilon \text{connex} \,.\, \text{E}\,!\, B'P \,.\, \text{Ɑ}'P \sim\epsilon 1 \,.\supset .$
$$P = B'P \leftarrow\!\!\!+ P \upharpoonright \text{Ɑ}'P \,.\, \text{Nr}'P = \dot{1} \dotplus \text{Nr}'(P \upharpoonright \text{Ɑ}'P)$$

with a similar proposition for $B'\breve{P}$ and $\text{D}'P$ ($*204{\cdot}461$).

We next prove that if P, Q are mutually exclusive series, their sum ($P \mathbin{\dot{+}} Q$) is a series, and vice versa ($*204{\cdot}5$); that if P is a series to which x does not belong, $P \rightarrow\!\!\!+ x$ and $x \leftarrow\!\!\!+ P$ are series, and vice versa ($*204{\cdot}51$); that if P is a series of mutually exclusive series, its sum $\Sigma'P$ is a series ($*204{\cdot}52$); that if P, Q are series, so is $P \times Q$ ($*204{\cdot}55$); that if P is a series of series, $\Pi'P$ is contained in diversity and is transitive ($*204{\cdot}561$), while if P is also well-ordered, *i.e.* such that every existent sub-class of $C'P$ has a first term, then $\Pi'P$ is a series ($*204{\cdot}57$); and that if P and Q are series, and Q is well-ordered, then P^Q and $P \exp Q$ are series ($*204{\cdot}59$). These propositions are essential to ordinal arithmetic, but they will not be referred to again until we reach that stage (Sections D and E of this Part).

We have next a collection of propositions ($*204{\cdot}6$—$\cdot 65$) on $p'\overrightarrow{P}``\alpha$ for various values of α, and finally three propositions on P_1. Two of these are much used, namely

$*204{\cdot}7.\quad \vdash : P \epsilon \text{Ser} \,.\supset .\, P_1 \epsilon 1 \rightarrow 1$

$*204{\cdot}71.\quad \vdash : P \epsilon \text{Ser} \,.\, xP_1 y \,.\supset .\, \overrightarrow{P}'y = \overrightarrow{P}'x \cup \iota'x$

$*204{\cdot}01.\quad \text{Ser} = \text{Rl}'J \cap \text{trans} \cap \text{connex} \quad \text{Df}$

$*204{\cdot}1.\quad \vdash : P \epsilon \text{Ser} \,.\equiv .\, P \subseteq J \,.\, P^2 \subseteq P \,.\, P \epsilon \text{connex} \,.$
$\equiv .\, P \epsilon \text{Rl}'J \,.\, P \epsilon \text{trans} \,.\, P \epsilon \text{connex} \quad [(*204{\cdot}01)]$

$*204{\cdot}11.\quad \vdash :. P \epsilon \text{Ser} \,.\equiv : P \subseteq J \,.\, P^2 \subseteq P : x \epsilon C'P \,.\supset_x .\, \overrightarrow{P}'x \cup \iota'x \cup \overleftarrow{P}'x = C'P$
$[*204{\cdot}1 \,.\, *202{\cdot}101]$

$*204{\cdot}12.\quad \vdash :: P \epsilon \text{Ser} \,.\equiv :. P \subseteq J \,.\, P^2 \subseteq P :. x, y \epsilon C'P \,.\supset_{x,y} :$
$xPy \,.\vee .\, x = y \,.\vee .\, yPx \quad [*204{\cdot}1 \,.\, *202{\cdot}103]$

$*204{\cdot}121.\quad \vdash :: P \epsilon \text{Ser} \,.\equiv :. P \subseteq J \,.\, P^2 \subseteq P :. x, y \epsilon C'P \,.\, x \neq y \,.\supset_{x,y} :$
$xPy \,.\vee .\, yPx \quad [*204{\cdot}1 \,.\, *202{\cdot}104]$

$*204{\cdot}13.\quad \vdash : P \epsilon \text{Ser} \,.\supset .\, P^2 \subseteq J \,.\, P \mathbin{\dot{\cap}} \breve{P} = \dot{\Lambda}$

Dem.

$\vdash .\, *204{\cdot}1 \,.\, *23{\cdot}44 \,.\supset \vdash : P \epsilon \text{Ser} \,.\supset .\, P^2 \subseteq J \,.\, P \epsilon \text{trans} \qquad (1)$
$\vdash .\, (1) \,.\, *201{\cdot}12 \,.\supset \vdash .\, \text{Prop}$

$*204{\cdot}14.\quad \vdash : P \epsilon \text{Ser} \,.\equiv .\, P \mathbin{\dot{\cap}} \breve{P} = \dot{\Lambda} \,.\, P^2 \subseteq P \,.\, P \epsilon \text{connex}$
$[*204{\cdot}1 \,.\, *50{\cdot}47]$

$[*200·31·41 . *201·411 . *202·411]$

The three following propositions deal with couples. Couples often require special treatment, owing to the fact that, if P is a couple, $P \upharpoonright \text{D}‘P = \dot{\Lambda}$, so that $C‘(P \upharpoonright \text{D}‘P) \neq \text{D}‘P$, whereas in any other case, if P is a series, $C‘(P \upharpoonright \text{D}‘P) = \text{D}‘P$. Hence the following propositions are often required.

***204·33.** $\vdash :. P \in \text{Ser} . x, y \in C`P . \supset : x \neq y . \overrightarrow{P}`y \subset \overrightarrow{P}`x . \equiv . yPx$

Dem.

$\vdash . *204 \cdot 32 . \supset \vdash :. \text{Hp} . \supset : x \neq y . \overrightarrow{P}`y \subset \overrightarrow{P}`x . \equiv . x \neq y . y \in \overrightarrow{P}`x \cup \iota`x .$

$[*51 \cdot 15] \qquad \equiv . x \neq y . y \in \overrightarrow{P}`x .$

$[\text{Hp}.*4 \cdot 71] \qquad \equiv . yPx :. \supset \vdash . \text{Prop}$

The three following propositions only require $P \in \text{Rl}`J \cap \text{connex}$, but are required for application to series, and are therefore convenient in the form here given.

***204·331.** $\vdash :. P \in \text{Ser} . x, y \in C`P . \supset : \overrightarrow{P}`x = \overrightarrow{P}`y . \equiv . x = y$
$[*202 \cdot 161 . *71 \cdot 55]$

***204·34.** $\vdash : P \in \text{Ser} . \supset . \overrightarrow{P} \upharpoonright C`P \in 1 \to 1 . \overrightarrow{P} \upharpoonright C`P \in (\overrightarrow{P} ; P) \overline{\text{smor}}\, P \quad [*202 \cdot 161]$

$*204\cdot35.\quad \vdash : P \in \mathrm{Ser} \,.\supset .\, \overrightarrow{P} ; P \ \mathrm{smor}\ P \quad [*204\cdot34]$

This proposition shows that the series of segments which have immediate successors is like the original series, for a segment whose immediate successor is x is $\overrightarrow{P}\text{‘}x$, and the series of such segments is $\overrightarrow{P};P$.

The following propositions ($*204\cdot4$—$\cdot44$) are concerned with relations with limited fields.

$*204\cdot4.\quad \vdash : P \in \mathrm{Ser} \,.\supset .\, P \upharpoonright \alpha \in \mathrm{Ser} \quad [*200\cdot33 \,.\, *201\cdot33 \,.\, *202\cdot33]$

$*204\cdot41.\quad \vdash : P, Q \in \mathrm{Ser} \,.\, Q \mathrel{\dot\subset} P \,.\supset .\, Q = P \upharpoonright C\text{‘}Q \quad [*202\cdot53 \,.\, *204\cdot13]$

In virtue of the above two propositions, the series contained in a given series are the relations resulting from limitations of the field; the process of limiting the field is merely the process of selecting a part of the original series without changing the order.

$*204\cdot42.\quad \vdash :. P \in \mathrm{Ser} \,.\supset : Q \in \mathrm{Ser} \,.\, Q \mathrel{\dot\subset} P \,.\equiv .\, (\exists \alpha) \,.\, Q = P \upharpoonright \alpha \,.\equiv .\, Q \in \mathrm{D}\text{‘}P\upharpoonright$
$[*204\cdot4\cdot41]$

$*204\cdot421.\quad \vdash : P \in \mathrm{Ser} \,.\supset .\, \mathrm{Ser} \cap \mathrm{Rl}\text{‘}P = \mathrm{D}\text{‘}P\upharpoonright \quad [*204\cdot42]$

$*204\cdot43.\quad \vdash : P^2 \mathrel{\dot\subset} P \,.\, P \mathrel{\dot\subset} J \,.\, Q \mathrel{\dot\subset} P \,.\, Q \in \mathrm{connex} \,.\supset .\, Q \in \mathrm{Ser}$

Dem.

The above proposition is used in $*274\cdot23$.

$*205$. MAXIMUM AND MINIMUM POINTS

Summary of $*205$.

The minimum points of a class α with respect to a relation P are those members of α which belong to the field of P but to which no members of α have the relation P; that is, they are those members of α which belong to $C`P$ but have no predecessors in $\alpha$. Similarly the maximum points of $\alpha$ are those members of $\alpha$ which belong to $C`P$ but have no successors in α. Both these notions have been already defined in $*93$, but they were there only used for the special purpose of studying generations. Their chief utility is in connection with *series*, and it is in this connection that we shall now consider them. Many of the properties of maxima and minima in series do not demand the whole hypothesis "$P \epsilon \mathrm{Ser}$," but only "$P \epsilon \mathrm{connex}$." This is the case, in particular, with the fundamental property of maxima and minima in series, namely that each class has at most one maximum and one minimum. The minimum of a class, if it exists, is the first term of the class, and the maximum, if it exists, is the last term. The maxima with respect to P are the minima with respect to $\breve{P}$; hence properties of maxima result immediately from the corresponding properties of minima, and will be set down without proof in what follows.

It will be seen that the maxima and minima of α depend only upon $\alpha \cap C`P$: the part of $\alpha$ (if any) which is not contained in $C`P$ is irrelevant.

In accordance with the definitions of $*93$, the class of minima of α is denoted by $\overrightarrow{\min_P}`\alpha$, where

$$\overrightarrow{\min_P}`\alpha = (\alpha \cap C`P) - \breve{P}``\alpha,$$

the definition being

$$\min_P = \hat{x}\hat{\alpha}\,\{x \,\epsilon\, (\alpha \cap C`P) - \breve{P}``\alpha\}.$$

Thus $\min_P$ is a relation contained in ϵ. When P is connected, we have $\overrightarrow{\min_P}`\alpha \,\epsilon\, 0 \cup 1$, *i.e.* (by $*71\cdot12$)

$$\min_P \epsilon\, 1 \rightarrow \mathrm{Cls}.$$

It follows that, if κ is a set of classes which all have minima, $\min_P \restriction \kappa$ is a selective relation for κ, *i.e.*

$$\min_P \restriction \kappa \,\epsilon\, \epsilon_\Delta`\kappa.$$

Owing to this fact, the existence of selections can sometimes be proved in dealing with series (especially with well-ordered series), in cases where such proof would be impossible if no serial arrangement were given.

The definition of $\min_P$ is so chosen as to exclude from $\overrightarrow{\min_P}`\alpha$ whatever part of $\alpha$ is not contained in $C`P$, and to make $\overrightarrow{\min_P}`\iota`x = \iota`x$, *i.e.* $\min_P`\iota`x = x$,

provided $x \in C'P . \sim(xPx)$. For these two reasons we have to reject two simpler definitions which might otherwise be thought preferable. One of these would give

$$\overrightarrow{\min_P}'\alpha = \alpha - \breve{P}''\alpha,$$

which might be obtained by putting

$$\min_P = \epsilon \dot{-} \epsilon \,|\, \breve{P} \quad \text{Df.}$$

This agrees with our definition whenever $\alpha \subset C'P$, but not otherwise, since it includes in $\overrightarrow{\min_P}'\alpha$ any part of α not contained in $C'P$. Hence it necessitates the hypothesis $\alpha \subset C'P$ in many propositions which, with our definition, do not require this hypothesis, and in particular in the proposition

$$P \in \text{connex} . \supset . \overrightarrow{\min_P}'\alpha \in 0 \cup 1,$$

so that instead of having (as with our definition)

$$P \in \text{connex} . \supset . \min_P \in 1 \to \text{Cls}$$

we should only have

$$P \in \text{connex} . \supset . \min_P \upharpoonright \text{Cl}'C'P \in 1 \to \text{Cls}.$$

For these reasons, this definition is less convenient than the one we have adopted.

The other definition which suggests itself is one which will give

$$\overrightarrow{\min_P}'\alpha = \overrightarrow{B}'P \upharpoonright \alpha.$$

If this definition were adopted, we might dispense with a special notation altogether, using $\overrightarrow{B}'P \upharpoonright \alpha$, $B'P \upharpoonright \alpha$ in place of $\overrightarrow{\min_P}'\alpha$, $\min_P'\alpha$. This definition, however, has the drawback that, if $\alpha \in 1$ and $P \in J$,

$$P \upharpoonright \alpha = \dot{\Lambda},$$

so that we have

$$\overrightarrow{\min_P}'\alpha = \dot{\Lambda} \text{ when } \alpha \in 1 . \alpha \subset C'P.$$

This necessitates the addition of the hypothesis $\alpha \sim \in 1$ (as in $*204{\cdot}45$ above, for example) in cases where, with our definition, no such hypothesis is required. If we take $\overrightarrow{B}'\alpha \upharpoonleft P$, instead of $\overrightarrow{B}'P \upharpoonright \alpha$, as the class of minimum points, we secure $\min_P'\iota'x = x$ when $P \in J$ and $x \in \text{D}'P$, but not when $x \in \overrightarrow{B}'\breve{P}$ Thus we still have exceptions to provide against which do not arise with the definition we have adopted.

The first few propositions of this number have already been proved in $*93$, but are repeated here for convenience of reference.

The propositions of this number are numerous and much used. Among the elementary properties of $\max_P$ and $\min_P$ with which the number begins, the following should be noted:

$*205{\cdot}12$. $\vdash . \overrightarrow{B}'P = \overrightarrow{\min_P}'\text{D}'P = \overrightarrow{\min_P}'C'P$

$*205\cdot123.\ \vdash : \overrightarrow{\max}_P{}^\backprime\alpha = \Lambda . \equiv . \alpha \cap C{}^\backprime P \subset P{}^{\backprime\backprime}\alpha$

$*205\cdot14.\ \ \vdash . \overrightarrow{\min}_P{}^\backprime\alpha = \hat{x}\{x \epsilon \alpha \cap C{}^\backprime P . \alpha \cap \overrightarrow{P}{}^\backprime x = \Lambda\}$

$*205\cdot15.\ \ \vdash . \overrightarrow{\min}_P{}^\backprime(\alpha \cap C{}^\backprime P) = \overrightarrow{\min}_P{}^\backprime\alpha$

$*205\cdot16.\ \ \vdash . \overrightarrow{\min}_P{}^\backprime\Lambda = \Lambda$

$*205\cdot18.\ \ \vdash : \sim(xPx) . x \epsilon C{}^\backprime P . \supset . \min_P{}^\backprime\iota{}^\backprime x = \max_P{}^\backprime\iota{}^\backprime x = x$

$*205\cdot19.\ \ \vdash : P \epsilon \text{trans} . \supset . \overrightarrow{\min}_P{}^\backprime\alpha = \overrightarrow{\min}_P{}^\backprime(\alpha \cup \breve{P}{}^{\backprime\backprime}\alpha) = \overrightarrow{\min}_P{}^\backprime\breve{P}_*{}^{\backprime\backprime}\alpha$

$*205\cdot194.\ \vdash : x \min_P \alpha . \supset . \sim(xPx)$

Owing to this proposition, we can sometimes dispense with the hypothesis $P \in J$ in propositions about minima which would otherwise require this hypothesis.

$*205\cdot197.\ \vdash :. P \epsilon \text{Rl}{}^\backprime J \cap \text{trans} . \supset : x \epsilon C{}^\backprime P . \equiv . x = \max_P{}^\backprime(\overrightarrow{P}{}^\backprime x \cup \iota{}^\backprime x)$

Our next set of propositions ($*205\cdot2$—$\cdot27$) introduces the hypothesis that P is connected, or transitive and connected. The chief of them are

$*205\cdot21.\ \ \vdash : P \epsilon \text{connex} . \text{E}\,! \min_P{}^\backprime\alpha . y \epsilon \alpha \cap C{}^\backprime P - \iota{}^\backprime\min_P{}^\backprime\alpha . \supset . \min_P{}^\backprime\alpha\, Py$

I.e. if the minimum of α exists, it precedes every other member of $\alpha \cap C{}^\backprime P$.

$*205\cdot22.\ \ \vdash : P \epsilon \text{trans} \cap \text{connex} . \text{E}\,! \min_P{}^\backprime\alpha . \supset . \breve{P}{}^{\backprime\backprime}\alpha = \overleftarrow{P}{}^\backprime\min_P{}^\backprime\alpha$

I.e. the terms which come after some part of α are those that come after its minimum (when the minimum exists).

$*205\cdot25.\ \ \vdash . \overrightarrow{\min}_P{}^\backprime\overleftarrow{P}{}^\backprime x = (\overleftarrow{P \dot{-} P^2}){}^\backprime x$

We have next the fundamental proposition:

$*205\cdot3.\ \ \ \vdash : P \epsilon \text{connex} . \supset . \overrightarrow{\min}_P{}^\backprime\alpha \epsilon 0 \cup 1 . \overrightarrow{\max}_P{}^\backprime\alpha \epsilon 0 \cup 1$

whence

$*205\cdot31.\ \ \vdash : P \epsilon \text{connex} . \supset . \min_P, \max_P \epsilon 1 \rightarrow \text{Cls}$

which leads to

$*205\cdot33.\ \ \vdash : P \epsilon \text{connex} . \kappa \subset \text{Cl}{}^\backprime\min_P . \supset . \min_P \upharpoonright \kappa \epsilon \epsilon_\Delta{}^\backprime\kappa$

This proposition is useful in the theory of well-ordered series. Observe that "$\kappa \subset \text{Cl}{}^\backprime\min_P$" means that κ consists of classes which have minima.

We have next a set of propositions ($*205\cdot4$—$\cdot44$) dealing with the relations of $\min_P{}^\backprime\alpha$ to $B{}^\backprime P \upharpoonright \alpha$ and $B{}^\backprime\alpha \rceil P$; next we have propositions on the relations of the minima of two different classes, of which the most useful is

$*205\cdot55.\ \ \vdash : P \epsilon \text{connex} . B{}^\backprime P \epsilon \alpha . \supset . B{}^\backprime P = \min_P{}^\backprime\alpha$

We have next various propositions on $p{}^\backprime\overrightarrow{P}{}^{\backprime\backprime}(\alpha \cap C{}^\backprime P)$, of which the chief is

$*205\cdot65.\ \ \vdash : P \epsilon \text{trans} \cap \text{connex} . \text{E}\,! \min_P{}^\backprime\alpha . \supset . p{}^\backprime\overrightarrow{P}{}^{\backprime\backprime}(\alpha \cap C{}^\backprime P) = \overrightarrow{P}{}^\backprime\min_P{}^\backprime\alpha$

I.e. the predecessors of the whole of a class contained in $C{}^\backprime P$ are the predecessors of its minimum (if it has one).

A useful proposition is

$*205{\cdot}68.\ \ \vdash : \breve{P}\text{“}\alpha \subset \alpha\ .\ \supset .\ \overrightarrow{\min}_P\text{‘}\alpha = \overrightarrow{\min}\,(P_{\text{po}})\text{‘}\alpha$

I.e. if α is a hereditary class, its minima with respect to P are the same as its minima with respect to P_{po}.

We prove next that if $P\text{“}\alpha$ has a maximum, so has α ($*205{\cdot}7$), and that if $P \epsilon \text{connex}$, only a unit class can have its maximum identical with its minimum ($*205{\cdot}73$).

$*205{\cdot}8$—$\cdot85$ are concerned with relation-arithmetic. The chief proposition here is

$*205{\cdot}8.\ \ \vdash : S \epsilon P \,\overline{\text{smor}}\, Q\ .\ \supset .\ \overrightarrow{\min}_P\text{‘}\alpha = S\text{“}\overrightarrow{\min}_Q\text{‘}\breve{S}\text{“}\alpha$

I.e. in any correlation, the minima of the correlates of a class are the correlates of the minima.

We end with two propositions on relations with limited fields. The more useful of these is

$*205{\cdot}9.\ \ \vdash : P \epsilon \text{connex}\ .\ \kappa \subset C\text{‘}P\ .\ \kappa \sim\epsilon 1\ .\ \supset .\ \overrightarrow{\min}\,(P \upharpoonright \kappa)\text{‘}\alpha = \overrightarrow{\min}_P\text{‘}(\alpha \cap \kappa)$

$*205{\cdot}1.\ \ \vdash : x \min_P \alpha\ .\ \equiv .\ x \epsilon \alpha \cap C\text{‘}P - \breve{P}\text{“}\alpha$ $\quad[*93{\cdot}11]$

$*205{\cdot}101.\ \ \vdash : x \max_P \alpha\ .\ \equiv .\ x \epsilon \alpha \cap C\text{‘}P - P\text{“}\alpha\ .\ \equiv .\ x \min\,(\breve{P})\,\alpha$ $\quad[*93{\cdot}115]$

$*205{\cdot}102.\ \ \vdash .\ \max_P = \min\,(\breve{P})$ $\quad[*93{\cdot}114]$

$*205{\cdot}11.\ \ \vdash .\ \overrightarrow{\min}_P\text{‘}\alpha = \alpha \cap C\text{‘}P - \breve{P}\text{“}\alpha$ $\quad[*93{\cdot}111]$

$*205{\cdot}111.\ \ \vdash .\ \overrightarrow{\max}_P\text{‘}\alpha = \alpha \cap C\text{‘}P - P\text{“}\alpha$ $\quad[*93{\cdot}116]$

$*205{\cdot}12.\ \ \vdash .\ \overrightarrow{B}\text{‘}P = \overrightarrow{\min}_P\text{‘}\text{D}\text{‘}P = \overrightarrow{\min}_P\text{‘}C\text{‘}P$ $\quad[*93{\cdot}112]$

$*205{\cdot}121.\ \ \vdash .\ \overrightarrow{B}\text{‘}\breve{P} = \overrightarrow{\max}_P\text{‘}\text{Ɑ}\text{‘}P = \overrightarrow{\max}_P\text{‘}C\text{‘}P$ $\quad[*93{\cdot}117]$

$*205{\cdot}122.\ \ \vdash : \overrightarrow{\min}_P\text{‘}\alpha = \Lambda\ .\ \equiv .\ \alpha \cap C\text{‘}P \subset \breve{P}\text{“}\alpha$ $\quad[*205{\cdot}11\ .\ *24{\cdot}3]$

$*205{\cdot}123.\ \ \vdash : \overrightarrow{\max}_P\text{‘}\alpha = \Lambda\ .\ \equiv .\ \alpha \cap C\text{‘}P \subset P\text{“}\alpha$

$*205{\cdot}13.\ \ \vdash .\ \overrightarrow{\min}_P\text{‘}\alpha \cup \breve{P}\text{“}\alpha = (\alpha \cap C\text{‘}P) \cup \breve{P}\text{“}\alpha$ $\quad[*22{\cdot}91\ .\ *205{\cdot}11]$

$*205{\cdot}131.\ \ \vdash .\ \overrightarrow{\max}_P\text{‘}\alpha \cup P\text{“}\alpha = (\alpha \cap C\text{‘}P) \cup P\text{“}\alpha$

$*205{\cdot}14.\ \ \vdash .\ \overrightarrow{\min}_P\text{‘}\alpha = \hat{x}\{x \epsilon \alpha \cap C\text{‘}P\ .\ \alpha \cap \overrightarrow{P}\text{‘}x = \Lambda\}$ $\quad[*37{\cdot}462\ .\ *205{\cdot}11]$

$*205{\cdot}141.\ \ \vdash .\ \overrightarrow{\max}_P\text{‘}\alpha = \hat{x}\{x \epsilon \alpha \cap C\text{‘}P\ .\ \alpha \cap \overleftarrow{P}\text{‘}x = \Lambda\}$

$*205{\cdot}15.\ \ \vdash .\ \overrightarrow{\min}_P\text{‘}(\alpha \cap C\text{‘}P) = \overrightarrow{\min}_P\text{‘}\alpha$ $\quad[*37{\cdot}265\ .\ *205{\cdot}11]$

$*205{\cdot}151.\ \ \vdash .\ \overrightarrow{\max}_P\text{‘}(\alpha \cap C\text{‘}P) = \overrightarrow{\max}_P\text{‘}\alpha$

$*205{\cdot}16.\ \ \vdash .\ \overrightarrow{\min}_P\text{‘}\Lambda = \Lambda$ $\quad[*205{\cdot}11\ .\ *24{\cdot}23]$

✳205·161. $\vdash . \overrightarrow{\max}_P\text{‘}\Lambda = \Lambda$

✳205·17. $\vdash :. x \in (\alpha \cap C\text{‘}P) . \supset_x . \sim(xPx) : \alpha \cap C\text{‘}P \in 1 : \supset .$

*206. SEQUENT POINTS

Summary of *206.

A "sequent" of a class α is a minimum of the terms that come after the whole of $\alpha \cap C'P$; that is, we put

$$\overrightarrow{\text{seq}}_P{}'\alpha = \overrightarrow{\text{min}}_P{}'p'\overleftarrow{P}``(\alpha \cap C'P).$$

Thus the sequents of α are its immediate successors. If α has a maximum, the sequents are the immediate successors of the maximum; but if α has no maximum, there will be no one term of α which is immediately succeeded by a sequent of α; in this case, if α has a single sequent, the sequent is the "upper limit" of α. Whenever P is connected, and therefore whenever P is serial, every class has one sequent or none with respect to P, by *205·3.

It will be seen that the sequents of α are the same as the sequents of $\alpha \cap C'P$, and therefore that $\overrightarrow{\text{seq}}_P{}'\alpha$ depends only upon $\alpha \cap C'P$: if α has terms not belonging to $C'P$, they are irrelevant.

For the immediate predecessors of a class α, we put

$$\overrightarrow{\text{prec}}_P{}'\alpha = \overrightarrow{\text{max}}_P{}'p'\overrightarrow{P}``(\alpha \cap C'P).$$

We have $\text{prec}_P = \text{seq}\,(\breve{P})$, so that propositions about prec_P result from those about seq_P by merely writing $\breve{P}$ in place of P; they will therefore not be given in what follows.

Among the elementary properties of seq_P with which this number begins, the following are the most important:

*206·13. $\vdash . \overrightarrow{\text{seq}}_P{}'\alpha = \overrightarrow{\text{min}}_P{}'p'\overleftarrow{P}``(\alpha \cap C'P)$

This merely embodies the definition.

*206·131. $\vdash . \overrightarrow{\text{seq}}_P{}'\alpha = \overrightarrow{\text{seq}}_P{}'(\alpha \cap C'P)$

*206·134. $\vdash . \overrightarrow{\text{seq}}_P{}'\alpha = C'P \cap \hat{x}\,\{\alpha \cap C'P \subset \overrightarrow{P}'x \,.\, \overrightarrow{P}'x \subset -p'\overleftarrow{P}``(\alpha \cap C'P)\}$

*206·14. $\vdash : \alpha \cap C'P = \Lambda \,.\, \supset . \overrightarrow{\text{seq}}_P{}'\alpha = \overrightarrow{B}'P$

Thus if P has a first term, this is the sequent of the null class, or of any other class which has no members in common with $C'P$.

*206·16. $\vdash : P \in \text{connex} \,.\, \supset . \overrightarrow{\text{seq}}_P{}'\alpha \in 0 \cup 1$

This follows at once from *205·3. It leads to

*206·161. $\vdash : P \in \text{connex} \,.\, \supset . \text{seq}_P \in 1 \rightarrow \text{Cls}$

Thus if P is a connected relation, no class has more than one sequent. This is not in general the case with relations which are not connected, even where the idea of sequents is quite naturally applicable. Take, *e.g.*, the relation of descendant to ancestor, and let α be the class of monarchs of England. Then $\overrightarrow{\mathrm{seq}}_P{}^{\boldsymbol{\prime}}\alpha$ will be such parents of monarchs as were not themselves monarchs.

***206·171.** $\vdash : P \epsilon \mathrm{connex} \,.\, P^2 \subseteq J \,.\, \supset .$

$$\overrightarrow{\mathrm{seq}}_P{}^{\boldsymbol{\prime}}\alpha = C{}^{\boldsymbol{\prime}}P \cap \hat{x} \{\alpha \cap C{}^{\boldsymbol{\prime}}P \subset \overrightarrow{P}{}^{\boldsymbol{\prime}}x \,.\, \overrightarrow{P}{}^{\boldsymbol{\prime}}x \subset (\alpha \cap C{}^{\boldsymbol{\prime}}P) \cup P{}^{\boldsymbol{\prime\prime}}\alpha\}$$

This proposition states that x is a sequent of α if the whole of $\alpha \cap C{}^{\boldsymbol{\prime}}P$ precedes x, but every term that precedes x either belongs to α or precedes some term of α. When P is a series and α has no maximum, we have

$$\overrightarrow{\mathrm{seq}}_P{}^{\boldsymbol{\prime}}\alpha = C{}^{\boldsymbol{\prime}}P \cap \hat{x}(\overrightarrow{P}{}^{\boldsymbol{\prime}}x = P{}^{\boldsymbol{\prime\prime}}\alpha) \quad (*206{\cdot}174),$$

i.e. the sequent of α, if any, is a term whose predecessors are identical with the predecessors of members of α. This is the case of a *limit* (cf. *207).

We have next a set of propositions (*206·211·28) concerned with $\overrightarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha$ and $\overleftarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha$. When P is transitive and connected, and α is an existent class contained in $C{}^{\boldsymbol{\prime}}P$ and having a sequent, we shall have

$$\overrightarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha = \alpha \cup P{}^{\boldsymbol{\prime\prime}}\alpha \,.\, \iota{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha \cup \overleftarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha = p{}^{\boldsymbol{\prime}}\overleftarrow{P}{}^{\boldsymbol{\prime\prime}}\alpha.$$

That is, the predecessors of the sequent are the members of α and the predecessors of members, while the sequent and its successors are the successors of the whole of α. The various parts of this statement require various parts of the hypothesis. Thus we have

***206·211.** $\vdash : \mathrm{E}\,!\, \mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha \,.\, \supset .\, \alpha \cap C{}^{\boldsymbol{\prime}}P \subset \overrightarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha$

***206·213.** $\vdash : P \epsilon \mathrm{connex} \,.\, \mathrm{E}\,!\, \mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha \,.\, \supset .\, \overrightarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha \subset (\alpha \cap C{}^{\boldsymbol{\prime}}P) \cup P{}^{\boldsymbol{\prime\prime}}\alpha$

***206·22.** $\vdash : P \epsilon \mathrm{trans} \cap \mathrm{connex} \,.\, \mathrm{E}\,!\, \mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha \,.\, \supset .$

$$\overrightarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha = (\alpha \cap C{}^{\boldsymbol{\prime}}P) \cup P{}^{\boldsymbol{\prime\prime}}\alpha = \overrightarrow{\mathrm{max}}_P{}^{\boldsymbol{\prime}}\alpha \cup P{}^{\boldsymbol{\prime\prime}}\alpha$$

***206·23.** $\vdash : P \epsilon \mathrm{trans} \cap \mathrm{connex} \,.\, \mathrm{E}\,!\, \mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha \,.\, \supset .$

$$\iota{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha \cup \overleftarrow{P}{}^{\boldsymbol{\prime}}\mathrm{seq}_P{}^{\boldsymbol{\prime}}\alpha = p{}^{\boldsymbol{\prime}}\overleftarrow{P}{}^{\boldsymbol{\prime\prime}}(\alpha \cap C{}^{\boldsymbol{\prime}}P) \cap C{}^{\boldsymbol{\prime}}P$$

If P is transitive, the value of $\overrightarrow{\mathrm{seq}}_P{}^{\boldsymbol{\prime}}\alpha$ is unchanged if we add to α any set of terms contained in $P{}^{\boldsymbol{\prime\prime}}\alpha$ (*206·24); thus in particular, $\overrightarrow{\mathrm{seq}}_P{}^{\boldsymbol{\prime}}(\alpha \cup P{}^{\boldsymbol{\prime\prime}}\alpha) = \overrightarrow{\mathrm{seq}}_P{}^{\boldsymbol{\prime}}\alpha$ (*206·25). Thus we can fill up any gaps in α, and take the whole series up to the end of α, without altering the sequent.

We have next a set of propositions (*206·3—·38) on the sequent of $P{}^{\boldsymbol{\prime\prime}}\alpha$, *i.e.* of the segment defined by α. If P is a series, $\mathrm{seq}_P{}^{\boldsymbol{\prime}}P{}^{\boldsymbol{\prime\prime}}\alpha$ is the maximum of α if α has a maximum, the sequent of α if α has a sequent but no maximum, and non-existent if α has neither a maximum nor a sequent (*206·35·331·36).

Our next set of propositions (*206·4—·52) concerns the sequents of unit classes, especially of ι'$\max_P$'α, and of classes of the form $\overrightarrow{P}$'x. We have

***206·4.** $\vdash : P \mathrel{\mathsf{G}} J \,.\, x \in C\text{'}P \,.\, \supset .\, x \operatorname{seq}_P \overrightarrow{P}\text{'}x$

***206·42.** $\vdash : x \in C\text{'}P \,.\, \supset .\, \overrightarrow{\operatorname{seq}_P}\text{'}\iota\text{'}x = \overleftarrow{P \dot{-} P^2}\text{'}x = \overrightarrow{\min_P}\text{'}\overleftarrow{P}\text{'}x$

whence the three following propositions:

***206·43.** $\vdash : P \in \text{trans} \cap \text{Rl}\text{'}J \,.\, x \in C\text{'}P \,.\, \supset .\, \overrightarrow{\operatorname{seq}_P}\text{'}\iota\text{'}x = \overleftarrow{P_1}\text{'}x$

***206·45.** $\vdash :.\, P \in \text{Ser} \,.\, x \in C\text{'}P \,.\, \supset : \text{E} ! \operatorname{seq}_P\text{'}\iota\text{'}x \,.\, \equiv .\, x \in \text{D}\text{'}P_1$

***206·46.** $\vdash : P \in \text{trans} \cap \text{connex} \,.\, \text{E} ! \max_P\text{'}\alpha \,.\, \supset .\, \overrightarrow{\operatorname{seq}_P}\text{'}\alpha = \overrightarrow{\operatorname{seq}_P}\text{'}\overrightarrow{\max_P}\text{'}\alpha$

From the above propositions it results that, when P is a series, any member of C'P is the sequent of the class of its predecessors, $\breve{P}_1$'x is the sequent of ι'x if either exists, and the sequent of a class which has a maximum is the immediate successor (if any) of the maximum, *i.e.*

***206·5.** $\vdash : P \in \text{trans} \cap \text{connex} \,.\, \text{E} ! \max_P\text{'}\alpha \,.\, \text{E} ! \operatorname{seq}_P\text{'}\alpha \,.\, \supset .\, \max_P\text{'}\alpha (P \dot{-} P^2) \operatorname{seq}_P\text{'}\alpha$

We then have a set of propositions (*206·53—·57) on the sequent of p'$\overrightarrow{P}$"$(\alpha \cap C\text{'}P)$, *i.e.* the sequent of the predecessors of the whole of $\alpha \cap C$'P. These propositions are specially useful in connection with "Dedekindian" series, *i.e.* series in which every class has either a maximum or a sequent (*214). These propositions all require the full hypothesis that P is a series. In this case, $\overrightarrow{\operatorname{seq}_P}\text{'}p\text{'}\overrightarrow{P}\text{"}(\alpha \cap C\text{'}P) = \overrightarrow{\min_P}\text{'}\alpha$, *i.e.* the sequent (if any) of the predecessors of the whole of $\alpha \cap C$'P is the minimum (if any) of α. Moreover by definition the maximum of p'$\overrightarrow{P}$"$(\alpha \cap C\text{'}P)$, if any, is the precedent of α. Hence α has either a minimum or a precedent if p'$\overrightarrow{P}$"$(\alpha \cap C\text{'}P)$ has either a sequent or a maximum (*206·54). Moreover the sequent and maximum of α are respectively (if they exist) the sequent and maximum of the predecessors of all the successors of the whole of $\alpha \cap C$'P (*206·551). Hence we arrive at the conclusion that the assumption that every class of the form p'$\overrightarrow{P}$"$(\alpha \cap C\text{'}P)$ has either a maximum or a sequent is equivalent both to the assumption that every class has either a maximum or a sequent (*206·56) and to the assumption that every class has either a minimum or a precedent (*206·55). It follows that these two latter assumptions are equivalent (*206·57), *i.e.* that a series is Dedekindian when, and only when, its converse is Dedekindian (*214·14).

We deal next (*206·6—·63) with correlations, showing that if two relations are correlated, the sequents of the correlates of any class are the correlates of the sequents, *i.e.*

***206·61.** $\vdash : S \in P \,\overline{\text{smor}}\, Q \,.\, \supset .\, \overrightarrow{\operatorname{seq}_P}\text{'}\alpha = S\text{"}\overrightarrow{\operatorname{seq}_Q}\text{'}\breve{S}\text{"}\alpha$

We end with a set of propositions ($*206{\cdot}7$—$\cdot732$) showing that the sequent of a class is unchanged if we remove from the class any term other than its maximum ($*206{\cdot}72$); that if a class has terms in $C\text{‘}P$, and has both a precedent and a sequent, the precedent has the relation P^2 to the sequent ($*206{\cdot}73$), and that the precedent is not identical with the sequent ($*206{\cdot}732$). These propositions are in the nature of lemmas, whose use is chiefly in the theory of stretches ($*215$).

$*206{\cdot}01.\quad \text{seq}_P = \hat{x}\hat{\alpha}\,\{x \min_P p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P)\}\quad$ Df

$*206{\cdot}02.\quad \text{prec}_P = \hat{x}\hat{\alpha}\,\{x \max_P p\text{‘}\overrightarrow{P}\text{“}(\alpha \cap C\text{‘}P)\}\quad$ Df

$*206{\cdot}1.\quad \vdash : x \,\text{seq}_P\, \alpha \,.\equiv .\, x \min_P p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P)\quad [(*206{\cdot}01)]$

$*206{\cdot}101.\quad \vdash .\, \text{prec}_P = \text{seq}\,(\breve{P})\qquad [*32{\cdot}241 \,.\, *33{\cdot}22 \,.\, *205{\cdot}102]$

We shall not enunciate any other propositions on prec_P (unless for some special reason), since the above proposition enables them to be immediately deduced from the corresponding propositions on seq_P.

$*206{\cdot}11.\quad \vdash : x \,\text{seq}_P\, \alpha \,.\equiv .\, x \in p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P) \cap C\text{‘}P - \breve{P}\text{“}p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P)$
$[*206{\cdot}1 \,.\, *205{\cdot}1]$

Observe that when $\alpha \cap C\text{‘}P$ is not null, $p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P) \subset C\text{‘}P$, so that the factor $C\text{‘}P$ on the right is unnecessary; but when $\alpha \cap C\text{‘}P = \Lambda$, we have $p\text{‘}\overleftarrow{P}\text{“}(\alpha \cap C\text{‘}P) = \text{V}$, so that the factor $C\text{‘}P$ becomes relevant. Owing to this factor, the sequents of Λ are $\overrightarrow{B}\text{‘}P$, so that if $B\text{‘}P$ exists, $B\text{‘}P$ is the sequent of Λ.

$*206{\cdot}12.\quad \vdash :: x \,\text{seq}_P\, \alpha \,. \equiv :.\, y \in \alpha \cap C\text{‘}P \,.\supset_y .\, yPx : x \in C\text{‘}P :.$

The propositions $*206\cdot173\cdot174$ deal with *limits.* When a class α has no maximum, *i.e.* when $\alpha \cap C\text{‘}P \subset P\text{‘‘}\alpha$, its sequent (if any) is called its *limit.* By the above propositions, the limit is a term x such that $\alpha \cap C\text{‘}P$ precedes x, but every predecessor of x precedes some member of $\alpha \cap C\text{‘}P$ ($*206\cdot173$); it is also a term x whose predecessors are identical with the predecessors of α ($*206\cdot174$). The subject of limits will be explicitly treated in $*207$.

$[*202\cdot103] \qquad \supset : \max_P`\alpha = \text{seq}_P`P``\alpha :. \supset \vdash . \text{Prop}$

In the hypothesis of $*206\cdot32$, we have both $\text{E} ! \max_P`\alpha$ and $\text{E} ! \text{seq}_P`P``\alpha$. So long as P is not contained in diversity, these are both necessary. For example, suppose we take

$$P = \alpha \uparrow (\alpha \cup \iota`x), \text{ where } x \sim \epsilon \alpha . \exists ! \alpha.$$

Then P is transitive and connected, but not contained in diversity. We have

$$\alpha \cup \iota`x = C`P . P``(\alpha \cup \iota`x) = \alpha = \text{D}`P.$$

Also $\quad \max_P{}^{\backprime}(\alpha \cup \iota{}^{\backprime}x) = x,$

$\overrightarrow{\mathrm{seq}}_P{}^{\backprime}P^{\backprime\backprime}(\alpha \cup \iota{}^{\backprime}x) = \overrightarrow{\min}_P{}^{\backprime}p{}^{\backprime}\overleftarrow{P}^{\backprime\backprime}\alpha = \overrightarrow{\min}_P{}^{\backprime}(\alpha \cup \iota{}^{\backprime}x) = \Lambda.$

Thus in this case $\max_P{}^{\backprime}(\alpha \cup \iota{}^{\backprime}x)$ exists, but $\mathrm{seq}_P{}^{\backprime}P^{\backprime\backprime}(\alpha \cup \iota{}^{\backprime}x)$ does not exist. When P is serial, *i.e.* when P is contained in diversity, in addition to being transitive and connected, the existence of $\max_P{}^{\backprime}\alpha$ involves that of $\mathrm{seq}_P{}^{\backprime}P^{\backprime\backprime}\alpha$, and therefore the hypothesis $\mathrm{E}\,!\,\mathrm{seq}_P{}^{\backprime}P^{\backprime\backprime}\alpha$, which appears in $*206{\cdot}32$, becomes unnecessary.

The condition $(\alpha) : \mathrm{E}\,!\, \mathrm{max}_P{}^{\backprime}\alpha \,.\, \mathrm{v} \,.\, \mathrm{E}\,!\, \mathrm{seq}_P{}^{\backprime}\alpha$ is the definition of what may be called "Dedekindian" series, *i.e.* series in which, when any division of the field into two parts is made in such a way that the first part wholly precedes the second, then either the first part has a last term or the second part has a first term. (When these alternatives are also mutually exclusive, the series has "Dedekindian continuity.") If α is any class, $P^{\backprime\backprime}\alpha$ is the segment of $C^{\backprime}P$ defined by α. In virtue of the above proposition, every segment of a Dedekindian series has a sequent. The sequent of a class having no maximum is what is commonly called a *limit*. Thus in a series having Dedekindian continuity (in which segments never have maxima), every segment has a limit.

$$(\alpha) . \alpha \in \text{ᗡ}\text{‘}\mathrm{max}_P \cup \text{ᗡ}\text{‘}\mathrm{seq}_P \quad [*206{\cdot}55{\cdot}56]$$

This proposition is important, since it shows that when a serial relation satisfies Dedekind's axiom, so does its converse. Thus if all classes which have no maximum have an upper limit, then all classes which have no minimum have a lower limit, and vice versa.

*207. LIMITS

Summary of *207.

A term x is said to be the "upper limit" of α in P if α has no maximum and x is the sequent of α. In this case, x immediately follows the class α, though there is no one member of α which x immediately follows. Sequents which are limits have special importance, and it is convenient to have a special notation for them. We write "$\mathrm{lt}_P{}^{\boldsymbol{\prime}}\alpha$" for the upper limit of α; or, if it is more convenient, "$\mathrm{lt}\,(P){}^{\boldsymbol{\prime}}\alpha$." (This is more convenient when P is replaced by an expression consisting of several letters, or by a letter with a suffix.) The *lower* limit of α will be the immediate predecessor of α when α has no minimum; this we denote by $\mathrm{tl}_P{}^{\boldsymbol{\prime}}\alpha$.

The following propositions on limits for the most part follow immediately from the propositions of *206 on sequents.

Our definition is so framed that the limit of the null-class is the first member of our series (if any). This departure from usage is convenient in order that, whenever our series contains any limiting point in the ordinary sense, the *series* of limiting points may exist, *i.e.* in order that $P \upharpoonleft \mathrm{D}{}^{\boldsymbol{\prime}}\mathrm{lt}_P$ may exist whenever there are existent parts of $C{}^{\boldsymbol{\prime}}P$ which have upper limits. The series $P \upharpoonleft \mathrm{D}{}^{\boldsymbol{\prime}}\mathrm{lt}_P$ is the "first derivative" of P. The definition of a limit is

$$\mathrm{lt}_P = \mathrm{seq}_P \upharpoonright (-\mathrm{G}{}^{\boldsymbol{\prime}}\mathrm{max}_P) \quad \mathrm{Df.}$$

Besides the limit, we require, for many purposes, a single notation for the "limit or maximum." This we denote by "limax_P," putting

$$\mathrm{limax}_P = \mathrm{max}_P \cup \mathrm{lt}_P \quad \mathrm{Df.}$$

Similarly for the lower limit or minimum we use "limin_P," putting

$$\mathrm{limin}_P = \mathrm{min}_P \cup \mathrm{tl}_P \quad \mathrm{Df.}$$

We have $\mathrm{tl}_P = \mathrm{lt}\,(\breve{P})$ (*207·101) and $\mathrm{limin}_P = \mathrm{limax}\,(\breve{P})$ (*207·401). Hence it is unnecessary to prove propositions concerning lower limits, since they result immediately from propositions concerning upper limits.

In virtue of our definition of a limit, x limits α if x is a sequent of α and α has no maximum (*207·1). Thus if α has a maximum, it has no limit (*207·11), but if it has no maximum, the class of its limits is the class of its sequents (*207·12). Thus the existence of the class of limits is equivalent to the existence of the class of sequents combined with the non-existence of the class of maxima, *i.e.*

***207·13.** $\vdash : \exists ! \overrightarrow{\mathrm{lt}_P}{}^{\boldsymbol{\prime}}\alpha \,.\equiv.\, \sim\exists ! \overrightarrow{\mathrm{max}_P}{}^{\boldsymbol{\prime}}\alpha \,.\, \exists ! \overrightarrow{\mathrm{seq}_P}{}^{\boldsymbol{\prime}}\alpha$

*207·2—·232 consist of various formulae for $\overrightarrow{\mathrm{lt}}_P$‘$\alpha$. We have

***207·2.** $\vdash : P \epsilon \text{connex} . x \,\mathrm{lt}_P\, \alpha . \supset . \alpha \cap C\text{‘}P \subset \overrightarrow{P}\text{‘}x . \overrightarrow{P}\text{‘}x \subset P\text{‘‘}\alpha$

I.e. the whole of $\alpha \cap C$‘P precedes x, but any predecessor of x precedes some member of α.

***207·231.** $\vdash : P \epsilon \text{Ser} . \exists ! \overrightarrow{\mathrm{lt}}_P\text{‘}\alpha . \supset . \overrightarrow{\mathrm{lt}}_P\text{‘}\alpha = C\text{‘}P \cap \hat{x}(\overrightarrow{P}\text{‘}x = P\text{‘‘}\alpha)$

I.e. the limit of α, if it exists, is the term whose predecessors are identical with the predecessors of some part of α.

We have also

***207·232.** $\vdash :. P \epsilon \text{Ser} . \supset : x = \mathrm{lt}_P\text{‘}\alpha . \equiv . x \epsilon C\text{‘}P - \alpha . \overrightarrow{P}\text{‘}x = P\text{‘‘}\alpha$

This proposition should be compared with *205·54, which (slightly re-written) is

$$\vdash :. P \epsilon \text{Ser} . \supset : x = \max_P\text{‘}\alpha . \equiv . x \epsilon C\text{‘}P \cap \alpha . \overrightarrow{P}\text{‘}x = P\text{‘‘}\alpha$$

From the two together we arrive at

***207·51.** $\vdash :. P \epsilon \text{Ser} . \supset : x = \mathrm{limax}_P\text{‘}\alpha . \equiv . x \epsilon C\text{‘}P . \overrightarrow{P}\text{‘}x = P\text{‘‘}\alpha$

which serves to illustrate the utility of "limax_P."

We have

***207·24.** $\vdash : P \epsilon \text{connex} . \supset . \overrightarrow{\mathrm{lt}}_P\text{‘}\alpha \epsilon 0 \cup 1 . \mathrm{lt}_P \epsilon 1 \rightarrow \text{Cls}$

I.e. if P is connected, a class cannot have more than one limit; also

***207·25.** $\vdash : P \epsilon \text{trans} . \beta \subset P\text{‘‘}\alpha . \supset . \overrightarrow{\mathrm{lt}}_P\text{‘}(\alpha \cup \beta) = \overrightarrow{\mathrm{lt}}_P\text{‘}\alpha$

I.e. any terms which have some α's beyond them may be added to α without altering the limit.

We next have a set of propositions (*207·251—·27) proving that if a class has a limit, any single term of the class may be removed without altering the limit (*207·261), and that in any case, provided the class is not a unit class, its minimum (if any) may be removed without altering the limit (*207·27). We then prove (*207·291) that if P is a series, and α is a class which has a limit, the predecessors of the limit are the class P_*‘‘α.

We then have a set of propositions (*207·3—·36) on the limit of $\overrightarrow{P}$‘x and kindred matters. If x has no immediate predecessor, the limit of $\overrightarrow{P}$‘x is x, and vice versa (*207·32·33). Hence

***207·35.** $\vdash : P \epsilon \text{Rl‘}J \cap \text{connex} . \supset . \text{D‘}\mathrm{lt}_P = C\text{‘}P - \text{Ɑ‘}(P \dot{-} P^2)$

I.e. the limit-points of P are those which have no immediate predecessors.

We next turn our attention to "limax_P." This again is one-many, provided P is connected (*207·41). We have by the definition

***207·42.** $\vdash : \exists ! \overrightarrow{\max}_P\text{‘}\alpha . \supset . \overrightarrow{\mathrm{limax}}_P\text{‘}\alpha = \overrightarrow{\max}_P\text{‘}\alpha$

*207·43. $\vdash : \overrightarrow{\max}_P{}'\alpha = \Lambda . \supset . \overrightarrow{\text{limax}}_P{}'\alpha = \overrightarrow{\text{seq}}_P{}'\alpha = \overrightarrow{\text{lt}}_P{}'\alpha$

*207·44. $\vdash . \text{Cl}'\text{limax}_P = \text{Cl}'\max_P \cup \text{Cl}'\text{lt}_P = \text{Cl}'\max_P \cup \text{Cl}'\text{seq}_P$

*207·45. $\vdash . \overrightarrow{\text{limax}}_P{}'\alpha = \overrightarrow{\max}_P{}'\alpha \cup \overrightarrow{\text{lt}}_P{}'\alpha$

Also we have

*207·46. $\vdash :. x = \text{limax}_P{}'\alpha . \equiv : x = \max_P{}'\alpha . \vee . x = \text{lt}_P{}'\alpha$

which is a very useful proposition, as is also *207·51 (given above).

A useful proposition in dealing with classes of classes contained in a series is

*207·54. $\vdash : P \in \text{Ser} . \kappa \subset \text{Cl}'\text{lt}_P . \supset . \overrightarrow{\text{limax}}_P{}'\text{lt}_P{}``\kappa = \overrightarrow{\text{limax}}_P{}'s'\kappa = \overrightarrow{\text{lt}}_P{}'s'\kappa$

I.e. if every member of κ has a limit, the limit or maximum (if any) of the limits is the limit or maximum, and in fact the limit, of $s'\kappa$.

We have next a set of propositions (*207·6—·66) on correlations, proving that the limit, or the limax, of the correlates is the correlate of the limit or limax, *i.e.*

*207·6. $\vdash : S \in P \,\overline{\text{smor}}\, Q . \supset . \overrightarrow{\text{lt}}_P{}'\alpha = S``\overrightarrow{\text{lt}}_Q{}'\breve{S}``\alpha$

*207·64. $\vdash : S \in P \,\overline{\text{smor}}\, Q . \supset . \overrightarrow{\text{limax}}_P{}'\alpha = S``\overrightarrow{\text{limax}}_Q{}'\breve{S}``\alpha$

The last three propositions (*207·7—·72) are lemmas for use in the theory of stretches (*215·5·51).

---

*207·01. $\text{lt}_P = \text{lt}(P) = \text{seq}_P \upharpoonright (-\text{Cl}'\max_P)$ Df

*207·02. $\text{tl}_P = \text{tl}(P) = \text{prec}_P \upharpoonright (-\text{Cl}'\min_P)$ Df

*207·03. $\text{limax}_P = \max_P \cup \text{lt}_P$ Df

*207·04. $\text{limin}_P = \min_P \cup \text{tl}_P$ Df

*207·1. $\vdash : x \,\text{lt}_P\, \alpha . \equiv . x \,\text{seq}_P\, \alpha . \sim \exists ! \overrightarrow{\max}_P{}'\alpha$ [(*207·01)]

*207·101. $\vdash . \text{tl}_P = \text{lt}(\breve{P})$ [*205·102 . *206·101 . (*207·02)]

We shall not give further propositions on lower limits, unless for some special reason, since all of them result from propositions on upper limits by means of *207·101.

*207·11. $\vdash : \exists ! \overrightarrow{\max}_P{}'\alpha . \supset . \overrightarrow{\text{lt}}_P{}'\alpha = \Lambda$ [*207·1]

*207·12. $\vdash : \overrightarrow{\max}_P{}'\alpha = \Lambda . \supset . \overrightarrow{\text{lt}}_P{}'\alpha = \overrightarrow{\text{seq}}_P{}'\alpha$ [*207·1]

*207·121. $\vdash : \alpha \cap C'P \subset P``\alpha . \supset . \overrightarrow{\text{lt}}_P{}'\alpha = \overrightarrow{\text{seq}}_P{}'\alpha$ [*207·12 . *205·123]

*207·13. $\vdash : \exists ! \overrightarrow{\text{lt}}_P{}'\alpha . \equiv . \sim \exists ! \overrightarrow{\max}_P{}'\alpha . \exists ! \overrightarrow{\text{seq}}_P{}'\alpha$ [*207·1]

*207·14. $\vdash :. \exists ! \overrightarrow{\max}_P{}'\alpha . \vee . \exists ! \overrightarrow{\text{seq}}_P{}'\alpha : \equiv : \exists ! \overrightarrow{\max}_P{}'\alpha . \vee . \exists ! \overrightarrow{\text{lt}}_P{}'\alpha$
[*207·13 . *5·63]

The above proposition is important because

$$(\alpha) : \exists ! \overrightarrow{\max_P}`\alpha \,.\vee.\, \exists ! \overrightarrow{\mathrm{lt}_P}`\alpha$$

is the characteristic of "Dedekindian" series, *i.e.* of such as fulfil Dedekind's axiom.

***207·15.** $\vdash : x \,\mathrm{lt}_P\, \alpha \,.\equiv.\, x \in C`P \,.\, \alpha \cap C`P \subset P``\alpha \cap \overrightarrow{P}`x \,.\, \overrightarrow{P}`x \subset -p`\overleftarrow{P}``(\alpha \cap C`P)$
[*207·1 . *205·123 . *206·134]

In virtue of this proposition, all limits are limits of classes of the form $\overrightarrow{P}‘x$. In this respect, limits (in general) differ from segments. If we call $P“\alpha$ the segment defined by α, there will in general be segments not of the form $\overrightarrow{P}‘x$. These, however, will be the segments which have no sequents, and therefore no limits; thus their existence does not introduce limits not derivable from classes of the form $\overrightarrow{P}‘x$.

$*208$. THE CORRELATION OF SERIES

Summary of $*208$.

The propositions of this number are chiefly important on account of their consequences in the theory of well-ordered series ($*250$ ff.) and in the theory of vector-families ($*330$ ff.). When two well-ordered series are ordinally similar, they have only one correlator; and a well-ordered series is not ordinally similar to any of its segments. Of these two propositions, the first is an immediate consequence of $*208 \cdot 41$, and the second is an immediate consequence of $*208 \cdot 47$.

Propositions concerning correlators of two relations P and Q are obtained from propositions concerning correlators of P with itself, by means of the fact that, if S, T are two correlators of P and Q, $S \mid \breve{T}$ is a correlator of P with itself. Again, correlators of P with itself are considered, in this number, as a special case of correlators of P with parts of itself. This latter is a notion which will prove important for other reasons than those for which it is used in our present context. If P is connected, and S correlates P with part of itself (so that $S ; P \subseteq P$), $C`P$ will contain terms of three kinds, (1) those for which $S`x = x$, (2) those for which $(S`x) P x$, (3) those for which $x P (S`x)$. Our propositions result from the non-existence (under certain circumstances) of maxima or minima of classes (2) and (3).

The following definition defines "correlations of P with parts (or the whole) of itself." The letters "cror" stand for "ordinal correlation." For a cardinal correlation, should occasion arise, we should use "cr," *i.e.* we should put

$$\mathrm{cr}`\alpha = s`\overline{\mathrm{sm}}\, \alpha``\mathrm{Cl}`\alpha \quad \mathrm{Df},$$

so that $\qquad S \in \mathrm{cr}`\alpha \,.\equiv.\, S \in 1 \rightarrow 1 \,.\, \mathrm{G}`S = \alpha \,.\, \mathrm{D}`S \subset \alpha.$

For the present, we are concerned with the corresponding ordinal notion; thus we require

$$S \in \mathrm{cror}`P \,.\equiv.\, S \in 1 \rightarrow 1 \,.\, \mathrm{G}`S = C`P \,.\, S ; P \subseteq P.$$

This is secured by putting

$$\mathrm{cror}`P = s`\overline{\mathrm{smor}}\, P``\mathrm{Rl}`P \quad \mathrm{Df}.$$

It will be observed that if α is what we called a "non-reflexive" class (cf. $*124$), $\mathrm{cr}`\alpha = \iota`I \upharpoonright \alpha$, and $S \in \mathrm{cr}`\alpha \,.\supset.\, \mathrm{D}`S = \alpha$. When $C`P$ is non-reflexive, the same is true of $P$; and when $C`P$ is reflexive, P is also reflexive, in the sense that it contains proper parts similar to itself, though if P is well-ordered, such proper parts cannot be *segments* of P, but must extend to the end of $C`P$.

The class of correlators of P with the whole of itself, *i.e.* $P \,\overline{\text{smor}}\, P$, is a sub-class of $\text{cror}'P$, and is specially important. This class differs widely in its properties from the corresponding cardinal class. If α has more than one member, the class $\alpha \,\overline{\text{sm}}\, \alpha$ (which is the "permutations" of α in the usual elementary sense) always has more than one member. But the class $P \,\overline{\text{smor}}\, P$ (which consists of such permutations of $C'P$ as keep the order unchanged) will consist of the single term $I \upharpoonright C'P$, unless $C'P$ contains classes which have neither a minimum nor a maximum, in which case there will be many correlators of P with itself. As a simple illustration, take the series of negative and positive integers in their natural order. Then if ν is any one of these integers, $+\nu$ is a correlator of the whole series with itself. If we take only the positive integers, $+\nu$ is no longer a correlator of the *whole* series with itself, since all integers less than ν are omitted from the correlate.

The first important use of the propositions of this number is in the beginning of the theory of well-ordered series ($*250$). The propositions there used are

$*208\cdot41$. $\vdash : P \epsilon \text{connex} \,.\, P^2 \subseteq J \,.\, \text{Cl ex}'C'P \subset \text{G}'\text{min}_P \cup \text{G}'\text{max}_P \,.$
$$P \,\text{smor}\, Q \,.\supset .\, (P \,\overline{\text{smor}}\, Q) \epsilon 1$$

I.e. if P is connected and asymmetrical, and every existent sub-class of $C'P$ has either a minimum or a maximum, P and Q cannot have more than one correlator.

$*208\cdot42$. In the same circumstances, $P \,\overline{\text{smor}}\, P = \iota'(I \upharpoonright C'P)$

$*208\cdot43$. $\vdash : \text{Cl ex}'C'P \subset \text{G}'\text{min}_P \,.\, S \epsilon \text{cror}'P \,.\supset .\, \sim(\exists x) \,.\, (S'x) \, P x$

I.e. if every existent sub-class of $C'P$ has a minimum, a correlator of P with part of itself can never move terms backwards. Thus for example, to take a simple instance, an infinite series consisting of some of the natural numbers in order of magnitude cannot have its μth term less than μ.

$*208\cdot45$. $\vdash : P \epsilon \text{connex} \,.\, \text{Cl ex}'C'P \subset \text{G}'\text{min}_P \cap \text{G}'\text{max}_P \,.\supset .\, \text{Rl}'P \cap \text{Nr}'P = \iota'P$

I.e. if P is connected and every existent sub-class of $C'P$ has both a maximum and a minimum, no proper part of P is similar to P. This proposition is important in the theory of finite series and finite ordinals.

$*208\cdot46$. $\vdash : \text{Cl ex}'C'P \subset \text{G}'\text{min}_P \,.\, S \epsilon \text{cror}'P \,.\supset .\, C'P \cap p'\overleftarrow{P}''\text{D}'S = \Lambda$

I.e. if every existent sub-class of $C'P$ has a minimum, a part of P which is similar to P must go up to the end of P, *i.e.* must not wholly precede any member of $C'P$.

$*208\cdot47$. $\vdash : \text{Cl ex}'C'P \subset \text{G}'\text{min}_P \,.\, Q \subseteq P \,.\, \exists ! \, C'P \cap p'\overleftarrow{P}''C'Q \,.\supset .\, \sim(Q \,\text{smor}\, P)$

This is an immediate consequence of $*208\cdot46$.

The proof of the above propositions proceeds simply by showing that if $S \epsilon \text{cror}'P$ and $(S'x) \, P x$, then $(S'S'x) \, P \, (S'x)$, so that x is not the earliest

term for which $(S\text{‘}x)\,Px$, since $S\text{‘}x$ is an earlier term for which the same thing holds. Hence $\hat{x}\,\{(S\text{‘}x)\,Px\}$ can have no minimum; and similarly $\hat{x}\,\{xP\,(S\text{‘}x)\}$ can have no maximum (∗208·14). So far we require no hypothesis as to P. Assuming now $P \in \text{connex} \,.\, P^2 \subseteq J$, we show similarly that if S correlates the whole of P with itself, $\hat{x}\,\{(S\text{‘}x)\,Px\}$ can have no maximum and $\hat{x}\,\{xP\,(S\text{‘}x)\}$ can have no minimum.

Propositions about correlators of P with Q follow from the above by taking two correlators S and T, and applying the above propositions to $S\,|\,\breve{T}$, which is a correlator of P with the whole of itself.

SECTION B

ON SECTIONS, SEGMENTS, STRETCHES, AND DERIVATIVES

Summary of Section B.

In this section, our chief topic will be *sections* and *segments*. This topic will occupy $*211$, $*212$ and $*213$, and $*210$ will consist of propositions whose chief utility lies in their application to segments. In $*214$, we shall consider Dedekindian series, which are intimately connected with segments, owing to the fact that one of the chief propositions in the subject is that the series of segments of a series is Dedekindian. In $*215$, we shall consider "stretches," which consist of any consecutive piece of a series, and are constituted by the product of an upper and lower section. Finally, in $*216$, we shall consider the derivative of a series, or of a class α contained in a series: the former is the series of limit-points of the series, *i.e.* $P \upharpoonright \mathrm{D}\text{`}\mathrm{lt}_P$, the latter is the class of limits of existent sub-classes of $\alpha \cap C\text{`}P$, *i.e.* $\mathrm{lt}_P\text{``}\mathrm{Cl\,ex}\text{`}(\alpha \cap C\text{`}P)$.

A class is called a *section* of P when it is contained in $C\text{`}P$, and contains all the predecessors of its members, *i.e.* $\alpha$ is a section of $P$ if $\alpha \subset C\text{`}P \,.\, P\text{``}\alpha \subset \alpha$. Thus a section consists of all the field up to a certain point. It may consist of all the predecessors of x, *i.e.* it may be of the form $\overrightarrow{P}\text{`}x$; or again, it may consist of these together with $x$, in which case it is of the form $\overrightarrow{P}\text{`}x \cup \iota\text{`}x$; or again, it may be not definable by means of a single sequent or maximum, but be of the form $P\text{``}\alpha$, where α is a class without a limit or maximum. The class of sections of P is denoted by $\mathrm{sect}\text{`}P$. A section of $\breve{P}$ will be called an "upper section" of P.

The idea of a *segment* is slightly less general than that of a *section.* We define a segment of P as any class of the form $P\text{``}\alpha$, *i.e.* as any member of $\mathrm{D}\text{`}P_\epsilon$. Provided $P$ is transitive, segments are contained among sections. But even in a series sections are not, in general, contained among segments: if $P$ is a series, and if $x$ is a member of $C\text{`}P$ which has no immediate successor, $\overrightarrow{P}\text{`}x \cup \iota\text{`}x$ will be a section but not a segment.

If a segment has a maximum, it must also have a sequent. Segments which have no maximum form a specially important class of segments: these are classes α such that $\alpha = P\text{``}\alpha$; they form the class $\mathrm{D}\text{`}(P_\epsilon \dot{\cap} I)$.

The properties of sections and segments considered as classes of classes are many and various: they are considered in $*211$. In $*212$, we pass to the consideration of the *series* of sections and segments. These series are

$P_{1c} \upharpoonright \text{sect}'P$ and $P_{1c} \upharpoonright D'P_\epsilon$ (cf. $*170$). The series of such segments as have no maximum is $P_{1c} \upharpoonright D'(P_\epsilon \dot{\frown} I)$. We put

$$\varsigma'P = P_{1c} \upharpoonright D'P_\epsilon \qquad \text{Df},$$

$$\text{sgm}'P = P_{1c} \upharpoonright D'(P_\epsilon \dot{\frown} I) \quad \text{Df}.$$

It then appears that

$$\varsigma'P_* = \text{sgm}'P_* = P_{1c} \upharpoonright \text{sect}'P,$$

so that it is unnecessary to introduce a special notation for the series of sections.

Whenever P is connected and transitive, $P_{1c} \upharpoonright D'P_\epsilon$ turns out to be equivalent to logical inclusion combined with diversity (with the field limited to $D'P_\epsilon$). That is to say ($*212{\cdot}23$),

$$\vdash : P \in \text{trans} \cap \text{connex} . \supset . \varsigma'P = \hat{\alpha}\hat{\beta} \{\alpha, \beta \in D'P_\epsilon . \alpha \subset \beta . \alpha \neq \beta\}.$$

Hence it follows ($*212{\cdot}24$) that

$$\vdash : P_* \in \text{connex} . \supset . \varsigma'P_* = \hat{\alpha}\hat{\beta} \{\alpha, \beta \in \text{sect}'P . \alpha \subset \beta . \alpha \neq \beta\}.$$

We have also ($*211{\cdot}6{\cdot}17$)

$$\vdash :. P_* \in \text{connex} . \alpha, \beta \in \text{sect}'P . \supset : \alpha \subset \beta . \vee . \beta \subset \alpha.$$

Hence it easily follows that whenever P_* is connected, $\varsigma'P_*$ is a series. Similarly $\varsigma'P$ will be a series if P is transitive and connected.

The fact of connection, which is required in order that $\varsigma'P$ or $\varsigma'P_*$ may be a series, results from

$$\alpha, \beta \in \text{sect}'P . \supset : \alpha \subset \beta . \vee . \beta \subset \alpha$$

or

$$\alpha, \beta \in D'P_\epsilon . \supset : \alpha \subset \beta . \vee . \beta \subset \alpha.$$

In order to deal with such cases generally, we study, in a preliminary number ($*210$), the consequences to be deduced from the hypothesis

$$\alpha, \beta \in \kappa . \supset_{\alpha, \beta} : \alpha \subset \beta . \vee . \beta \subset \alpha.$$

We find that, with this hypothesis, putting

$$Q = \hat{\alpha}\hat{\beta} (\alpha, \beta \in \kappa . \alpha \subset \beta . \alpha \neq \beta),$$

$Q = P_{1c} \upharpoonright \kappa$ if $\kappa \subset \text{Cl}'C'P$ ($*210{\cdot}13$), and thus in the same circumstances $P_{1c} \upharpoonright \kappa$ is a series ($*210{\cdot}14$).

The interesting point about such series is their behaviour with regard to limits. Assuming that κ is not a unit class (so as to insure $\dot{\exists} ! Q$), if λ is any sub-class of κ, the logical product $p'\lambda$ is the minimum of λ if it is a member of λ ($*210{\cdot}21$), and the lower limit of λ if it is a member of κ but not of λ ($*210{\cdot}23$). Similarly $s'\lambda$ is the maximum of λ if it is a member of λ ($*210{\cdot}211$), and the upper limit of λ if it is not a member of λ but is a member of κ ($*210{\cdot}231$). Thus if κ is such that, whenever $\lambda \subset \kappa$, we have $s'\lambda \in \kappa$, it follows that every sub-class of κ has either a maximum or a limit, *i.e.* the series $P_{1c} \upharpoonright \kappa$ is Dedekindian. Now each of the three classes $\text{sect}'P$, $D'P_\epsilon$, $D'(P_\epsilon \dot{\frown} I)$ verifies this condition, *i.e.* the sum of any sub-class of any one of these classes belongs to the class in question ($*211{\cdot}63{\cdot}64{\cdot}65$). (This

holds without any hypothesis as to P.) Hence we arrive at the result that $\varsigma`P_*$ (*i.e.* the series of sections) is a Dedekindian series whenever $P_*$ is connected and $P$ is not null ($*214\cdot32$), while $\varsigma`P$ (*i.e.* the series of segments) is a Dedekindian series whenever P is transitive and connected and not null ($*214\cdot33$), and $\text{sgm}`P$ (the series of segments having no maximum) is a Dedekindian series whenever it exists and P is connected ($*214\cdot34$). These propositions are important, and are the source of much of the utility of sections and segments.

For many purposes, especially in ordinal arithmetic, it is necessary to consider sections not as classes, but as series. That is to say, if α is a member of $\text{sect}`P$, we want to deal with $P \upharpoonright \alpha$ rather than with $\alpha$. The series of all such terms as $P \upharpoonright \alpha$ might be supposed to be $P \upharpoonright ; \varsigma`P_*$. But here a limitation is necessary owing to the fact that, if $B`P$ exists, $\Lambda$ and $\iota`B`P$ are both sections, and $P \upharpoonright \Lambda$ and $P \upharpoonright \iota`B`P$ are both $\dot{\Lambda}$, so that $P \upharpoonright ; \varsigma`P_*$ will be a relation which $\dot{\Lambda}$ will have to itself. In order to avoid this, we first exclude Λ from the sections to be considered, and thus put

$$P_\varsigma = P \upharpoonright ;(\varsigma`P_*) \upharpoonright (-\iota`\Lambda) \quad \text{Df.}$$

Then P_ς is the series of sections considered as series. Provided P_{po} is a series, the relation P_ς holds between any two members Q and R of its field when, and only when, $Q \subset R \,.\, Q \neq R$. The subject of P_ς is considered in $*213$; the utility of the propositions of this number will not appear until we come to ordinal arithmetic.

The subject of Dedekindian relations is next considered ($*214$). We define a Dedekindian relation as one such that every class has either a maximum or a sequent. A Dedekindian series must have a first and a last term, since the first term must be the sequent of Λ, and the last must be the maximum of the field. A Dedekindian series may be discrete, or compact (*i.e.* such that there is a term between any two, *i.e.* such that $P^2 = P$), or partly one and partly the other. A finite series must be Dedekindian: a well-ordered series is Dedekindian if it has a last term. But the chief importance of the Dedekindian property is in connection with compact series. A compact Dedekindian series is said to possess "Dedekindian continuity"; such series have many important properties. They are a wider class than series possessing Cantorian continuity; these latter will be considered in Section F of this Part.

$*210$. ON SERIES OF CLASSES GENERATED BY THE RELATION OF INCLUSION

Summary of $*210$.

In the theory of series it frequently happens that we have to deal with a class of classes such that, of any two, one is contained in the other. *I.e.* if κ is the class of classes, we have

$$\alpha, \beta \in \kappa . \supset_{\alpha, \beta} : \alpha \subset \beta . \vee . \beta \subset \alpha.$$

Instances of this are afforded by the various classes of sections, to be considered in $*211$. When κ fulfils the above condition, the classes composing κ can be arranged in a series by the relation of inclusion (combined with inequality), *i.e.* by the relation

$$\hat{\alpha}\hat{\beta}\,(\alpha, \beta \in \kappa . \alpha \subset \beta . \alpha \neq \beta),$$

or, what comes to the same,

$$\hat{\alpha}\hat{\beta}\,(\alpha, \beta \in \kappa . \exists ! \beta - \alpha).$$

If P is any relation such that $\kappa \subset \mathrm{Cl}`C`P$, the above relation of inclusion is equal to

$$P_{1c} \upharpoonright \kappa.$$

(For the definition of P_{1c}, see $*170$.) Thus under the above circumstances, $P_{1c} \upharpoonright \kappa$ is a series, whatever P may be.

The importance of such relations of inclusion, as generators of series, is in connection with the existence of maxima and minima or limits. If we put

$$Q = \hat{\alpha}\hat{\beta}\,(\alpha, \beta \in \kappa . \exists ! \beta - \alpha),$$

where κ satisfies the above condition, then if $\lambda \subset \kappa$, and if $s`\lambda \in \kappa$, $s`\lambda$ is the maximum or the upper limit of λ with respect to Q, according as $s`\lambda$ is a member of $\lambda$ or not. Similarly if $p`\lambda \in \kappa$, $p`\lambda$ is the minimum or lower limit of $\lambda$, according as $p`\lambda$ is a member of λ or not. Hence if κ is such that the sum of any sub-class of κ is a member of κ, every sub-class of κ has either a maximum or an upper limit; and if the product of every sub-class of κ is a member of κ, every sub-class of κ has either a minimum or a lower limit.

In order that every sub-class of κ should have a minimum or a lower limit, it is sufficient that the *sum* of every sub-class of κ should be a member of κ. For, if λ is any sub-class of κ, ccnsider those members of κ which are contained in $p`\lambda$, *i.e.*

$$\kappa \cap \mathrm{Cl}`p`\lambda.$$

If $p`\lambda \in \kappa$, the sum of these classes $= p`\lambda$, and is the lower limit or minimum of κ. But if $p`\lambda \sim \in \kappa$, then every member of $\kappa$ which is not contained in $s`(\kappa \cap \mathrm{Cl}`p`\lambda)$ is also not contained in $p`\lambda$, and is therefore not contained in some member of $\lambda$. Hence $s`(\kappa \cap \mathrm{Cl}`p`\lambda)$ is the lower limit of λ.

It is owing to these propositions that segments of series are of such great importance in connection with limits.

The hypothesis that if $\lambda \subset \kappa$, $p'\lambda$ is a member of κ, will usually fail to be verified in the case when $\lambda = \Lambda$, since in this case $p'\lambda = \mathrm{V}$. But all the results desired can be obtained from the hypothesis that, if $\lambda \subset \kappa$, $(p'\lambda \cap s'\kappa) \in \kappa$. This hypothesis is equivalent to the other except in the case of Λ, in which case it requires $s'\kappa \in \kappa$, which is much more often verified than $\mathrm{V} \in \kappa$, which was required by the other hypothesis.

The principal propositions of this number are the following:

$*210{\cdot}1.\quad \vdash :: \alpha, \beta \in \kappa \,.\supset_{\alpha,\beta} : \alpha \subset \beta \,.\vee.\, \beta \subset \alpha :.\supset :.\, \alpha, \beta \in \kappa \,.\supset : \alpha \subset \beta \,.\, \alpha \neq \beta \,.\equiv.\, \exists ! \beta - \alpha$

$*210{\cdot}11.\quad \vdash : Q = \hat{\alpha}\hat{\beta}(\alpha, \beta \in \kappa \,.\, \alpha \subset \beta \,.\, \alpha \neq \beta) \,.\supset.\, Q \in \mathrm{trans} \cap \mathrm{Rl}'J$

$*210{\cdot}12.\quad \vdash : \mathrm{Hp}\, *210{\cdot}1{\cdot}11 \,.\supset.\, Q \in \mathrm{Ser}$

$*210{\cdot}13.\quad \vdash : \mathrm{Hp}\, *210{\cdot}12 \,.\, \kappa \subset \mathrm{Cl}'C'P \,.\supset.\, Q = P_{\mathrm{lc}} \upharpoonright \kappa$

$*210{\cdot}2.\quad \vdash : \mathrm{Hp}\, *210{\cdot}12 \,.\, \kappa \sim\in 1 \,.\supset.\, \overrightarrow{\min}_Q{}'\lambda = \lambda \cap \kappa \cap \iota' p'(\lambda \cap \kappa)$

$*210{\cdot}21.\quad \vdash : \mathrm{Hp}\, *210{\cdot}2 \,.\, \lambda \subset \kappa \,.\, p'\lambda \in \lambda \,.\supset.\, \min_Q{}'\lambda = p'\lambda$

$*210{\cdot}211$ gives an analogous proposition for $s'\lambda$ and $\max_Q$. We shall not here mention such analogues, unless for some special reason.

$*210{\cdot}23.\quad \vdash : \mathrm{Hp}\, *210{\cdot}2 \,.\, \lambda \subset \kappa \,.\, p'\lambda \in \kappa - \lambda \,.\supset.\, p'\lambda = \mathrm{prec}_Q{}'\lambda = \mathrm{tl}_Q{}'\lambda$

$*210{\cdot}232.\quad \vdash : \mathrm{Hp}\, *210{\cdot}2 \,.\, \lambda \subset \kappa \,.\, p'\lambda \in \kappa \,.\supset.\, p'\lambda = \mathrm{limin}_P{}'\lambda$

$*210{\cdot}251.\quad \vdash :.\, \mathrm{Hp}\, *210{\cdot}2 : \lambda \subset \kappa \,.\supset_\lambda.\, s'\lambda \in \kappa : \supset : \lambda \subset \kappa \,.\supset.\, s'\lambda \in (\overrightarrow{\max}_Q{}'\lambda \cup \overrightarrow{\mathrm{seq}}_Q{}'\lambda)$

$*210{\cdot}252.\quad \vdash :.\, \mathrm{Hp}\, *210{\cdot}2 : \lambda \subset \kappa \,.\supset_\lambda.\, p'\lambda \cap s'\kappa \in \kappa : \supset :$

$$s'(\kappa \cap \mathrm{Cl}'p'\lambda) = \mathrm{prec}_Q{}'\lambda$$

$*210{\cdot}28.\quad \vdash : \mathrm{Hp}\, *210{\cdot}2 \,.\, s''\mathrm{Cl}'\kappa \subset \kappa \,.\supset.$

$$(\lambda) \,.\, \lambda \in (\text{Ɑ}'\max_Q \cup \text{Ɑ}'\mathrm{seq}_Q) \cap (\text{Ɑ}'\min_Q \cup \text{Ɑ}'\mathrm{prec}_Q)$$

Thus if κ is a class of not less than two classes such that, of any two of its members, one must be contained in the other, and if Q is the relation $\alpha \subset \beta \,.\, \alpha \neq \beta$ confined to members of κ, then Q is a series ($*210{\cdot}12$) in which, provided the sums of sub-classes of κ are always members of κ, every class has either a maximum or an upper limit, and every class has either a minimum or a lower limit ($*210{\cdot}28$).

The reader will observe that, if $\alpha, \beta \in \kappa \,.\supset_{\alpha,\beta} : \alpha \subset \beta \,.\vee.\, \beta \subset \alpha$, any *finite* sub-class of κ must contain its own sum and product as members. For example, if we have two classes α and β, if $\alpha \subset \beta$, then $\alpha = p'(\iota'\alpha \cup \iota'\beta)$ and $\beta = s'(\iota'\alpha \cup \iota'\beta)$; if we have three classes α, β, γ, and $\alpha \subset \beta \,.\, \beta \subset \gamma$, then

$\alpha = p\text{‘}(\iota\text{‘}\alpha \cup \iota\text{‘}\beta \cup \iota\text{‘}\gamma)$ and $\gamma = s\text{‘}(\iota\text{‘}\alpha \cup \iota\text{‘}\beta \cup \iota\text{‘}\gamma)$; and so on. Thus the hypothesis $s\text{‘‘}\mathrm{Cl}\text{‘}\kappa \subset \kappa$ is only required in order to enable us to deal with infinite snb-classes of κ.

This proposition is more useful than *210·25, because its hypothesis is much oftener verified. In order that the hypothesis of *210·25 may be verified, we must have $\text{V} \in \kappa$, since $\Lambda \subset \kappa \,.\, p`\Lambda = \text{V}$; hence we must also have $s`\kappa = \text{V}$. But the hypothesis of *210·252 only requires, as far as Λ is concerned, that we should have $s`\kappa \in \kappa$.

$*$211. ON SECTIONS AND SEGMENTS

Summary of $*$211.

The theory of the modes of separation of a series into two classes, one of which wholly precedes the other, and which together make up the whole series, is of fundamental importance. When one out of a pair of such classes is given, the other is the rest of the series; we may therefore, for most purposes, confine our attention to that one of the two classes which comes first in the serial order. Any class which can be the first of such a pair we shall call a *section* of our series. If P is the series, we shall denote the class of its sections by "sect'P." If α is a section of P, we shall call $C'P - \alpha$ (which is the second class of our pair) the *complement* of α. The class of complements of sections is

$$(C'P -)``\text{sect}'P,$$

which is identical with sect'$\breve{P}$ ($*$211·75).

In order that a class may be a section of P, it is necessary and sufficient that it should be contained in $C'P$ and should contain all its own predecessors; thus we put

$$\text{sect}'P = \hat{\alpha}(\alpha \subset C'P \,.\, P``\alpha \subset \alpha) \quad \text{Df.}$$

We have also, by $*$90·23,

$$\text{sect}'P = \hat{\alpha}\,(\alpha = P_*``\alpha) \quad (*211\cdot13).$$

Among sections, a specially important class consists of classes which are composed of all the predecessors of some class, *i.e.* classes of the form $P``\beta$, *i.e.* classes which are members of $\text{D}'P_\epsilon$. Whenever $P$ is transitive, $P``P``\beta \subset P``\beta$; hence $P``\beta$ is a section according to the above definition. When $P$ is a series, the complement of $P``\beta$ (when β exists and is contained in $C'P$) is

$$\overrightarrow{\text{max}}_P{}'\beta \cup p'\overleftarrow{P}``\beta.$$

The members of $\text{D}'P_\epsilon$ are called *segments* of the series generated by P. In a series in which every sub-class has a maximum or a sequent, $\text{D}'P_\epsilon = \overrightarrow{P}``C'P$ ($*$211·38), *i.e.* the predecessors of a class are always the predecessors of a single term, namely the maximum of the class if it exists, or the sequent if no maximum exists. But if there are classes which have neither a maximum nor a sequent, the predecessors of such classes are not coextensive with the predecessors of any single term. Thus in general the series of segments will be larger than the original series. For example, if our original series is of the type of the series of rationals in order of magnitude, the series of segments is of the type of the series of real numbers, *i.e.* the type of the continuum.

Among segments, a specially important class consists of those which have no maximum. In this case, if α is such a segment, we have $\alpha \subset P``\alpha$; and since (provided $P$ is transitive) we also have, for all segments, $P``\alpha \subset \alpha$, the segments having no maximum are those for which $\alpha = P``\alpha$, *i.e.* they are the class $D`(P_\epsilon \dot{\wedge} I)$. In compact series, all segments belong to this latter class, but in general only those segments belong to it which correspond to a "Häufungsstelle." In all cases in which the existence of a limit is not known, the segment fulfils the functions of a limit; that is to say, in those places in the series where a limit might be expected, we have a segment having no limit or maximum, which takes the same place in the series of segments as would be taken by the limit in the original series if the limit existed. Segments having no limit or maximum are limiting points in the series of segments, and every class of segments which has no maximum in the series of segments has a limit in that series.

We have thus three classes to deal with, namely

(1) $\text{sect}`P$,

(2) $D`P_\epsilon$,

(3) $D`(P_\epsilon \dot{\wedge} I)$.

Of these the second is contained in the first when P is transitive (*211·15), and the third is contained in the first and second (*211·14). The second consists of those members of the first which have either a sequent or no maximum (*211·32); the third consists of those members of the first which have no maximum (*211·41). If every member of the third class has a limit, *i.e.* if

$$D`(P_\epsilon \dot{\wedge} I) \subset \text{G}`\text{seq}_P,$$

then every class has either a sequent or a maximum, *i.e.* the series is Dedekindian; and the converse also holds (*211·47).

When P is connected, of any two sections one must be contained in the other (*211·6). Moreover, if λ is contained in any one of the three classes $\text{sect}`P$, $D`P_\epsilon$, $D`(P_\epsilon \dot{\wedge} I)$, then $s`\lambda$ is a member of that class (*211·63·64·65). Hence the propositions of *210 become available. It is thus that the existence of limits in series of segments or sections is proved: the maximum or upper limit of any class λ consisting of segments or sections is $s`\lambda$, and the minimum or lower limit is the sum of the segments that are contained in every λ.

We begin, in this number, with elementary properties of $\text{sect}`P$. The sections of P are the segments of P_* (*211·13) and the sections of P_{po} (*211·17). We have

***211·26.** $\vdash . C`P \in \text{sect}`P . s`\text{sect}`P = C`P$

We then proceed to the elementary properties of segments, *i.e.* of $D`P_\epsilon$ (*211·3—·38). We have

$*211\cdot3.\quad \vdash . \overrightarrow{P}``C`P \subset \mathrm{D}`P_\epsilon$

$*211\cdot301.\quad \vdash . \mathrm{D}`P \epsilon \mathrm{D}`P_\epsilon$

$*211\cdot302.\quad \vdash : P \epsilon \mathrm{Ser} . \supset . \overrightarrow{P}``C`P = \mathrm{sect}`P \cap \mathrm{Cl}`\mathrm{seq}_P$

$*211\cdot351.\quad \vdash : P \epsilon \mathrm{Ser} . \supset . \mathrm{sect}`P - \mathrm{D}`P_\epsilon = \overrightarrow{P_*}``(C`P - \mathrm{D}`P_1)$

We then proceed to elementary properties of segments having no maximum, *i.e.* of $\mathrm{D}`(P_\epsilon \dot{\cap} I)$ ($*211\cdot4$—$\cdot47$). We have

$*211\cdot42.\quad \vdash : P \epsilon \mathrm{trans} . \supset . \mathrm{D}`(P_\epsilon \dot{\cap} I) = \mathrm{D}`P_\epsilon - \mathrm{Cl}`\mathrm{max}_P$

$*211\cdot44.\quad \vdash . \Lambda \epsilon \mathrm{D}`(P_\epsilon \dot{\cap} I) . \Lambda \epsilon \mathrm{D}`P_\epsilon . \Lambda \epsilon \mathrm{sect}`P$

$*211\cdot451.\quad \vdash : \overrightarrow{P}`x \epsilon \mathrm{D}`(P_\epsilon \dot{\cap} I) . \supset . x \sim\epsilon \mathrm{Cl}`(P \dot{-} P^2)$

Our next set of propositions ($*211\cdot5$—$\cdot553$) is concerned with compact series, *i.e.* with the hypothesis $P^2 = P$. We have

$*211\cdot51.\quad \vdash : P^2 = P . \supset . \mathrm{D}`P_\epsilon = \mathrm{D}`(P_\epsilon \dot{\cap} I)$

$*211\cdot551.\quad \vdash :. P \epsilon \mathrm{Ser} . \supset : \mathrm{Cl}`\mathrm{max}_P \cap \mathrm{Cl}`\mathrm{seq}_P = \Lambda . \equiv . P = P^2$

I.e. a series is compact when, and only when, no class has both a maximum and a sequent.

We come next to the application of the propositions of $*210$ ($*211\cdot56$—$\cdot692$). These propositions proceed from

$*211\cdot56.\quad \vdash :. P \epsilon \mathrm{connex} . \alpha, \beta \epsilon \mathrm{sect}`P . \supset : \alpha \subset \beta . \vee . \beta \subset P``\alpha$

(Here "$P_{\mathrm{po}} \epsilon \mathrm{connex}$" may be substituted in the hypothesis: cf. $*211\cdot561$.) The propositions of this set, which are very important, have been already mentioned.

Our next set of propositions ($*211\cdot7$—$\cdot762$) are concerned with the complements of sections and segments. Some of these propositions have been already mentioned; others of importance are:

$*211\cdot7.\quad \vdash : \alpha \epsilon \mathrm{sect}`P . \supset . C`P - \alpha \epsilon \mathrm{sect}`\breve{P}$

$*211\cdot703.\quad \vdash : P \epsilon \mathrm{connex} . \alpha \epsilon \mathrm{sect}`P - \iota`C`P . \supset . \exists ! p`\overleftarrow{P}``\alpha$

$*211\cdot726.\quad \vdash : P \epsilon \mathrm{connex} \cap \mathrm{Rl}`J . \alpha \epsilon \mathrm{sect}`P . \supset .$
$$\overrightarrow{\mathrm{max}_P}`\alpha = \overrightarrow{\mathrm{prec}_P}`(C`P - \alpha) . \overrightarrow{\mathrm{seq}_P}`\alpha = \overrightarrow{\mathrm{min}_P}`(C`P - \alpha)$$

$*211\cdot727.\quad \vdash :. P \epsilon \mathrm{connex} \cap \mathrm{Rl}`J . \alpha \epsilon \mathrm{sect}`P . \supset :$
$$\mathrm{E} ! \mathrm{limax}_P`\alpha . \equiv . \mathrm{E} ! \mathrm{limin}_P`(C`P - \alpha)$$

$*211\cdot728.\quad \vdash :. P \epsilon \mathrm{connex} \cap \mathrm{Rl}`J . \alpha \epsilon \mathrm{sect}`P : \sim\mathrm{E} ! \mathrm{max}_P`\alpha . \vee .$
$$\sim\mathrm{E} ! \mathrm{min}_P`(C`P - \alpha) : \supset . \overrightarrow{\mathrm{limax}_P}`\alpha = \overrightarrow{\mathrm{limin}_P}`(C`P - \alpha)$$

The remaining propositions are mainly occupied with relation-arithmetic. The most important of them is

$*211{\cdot}82.\ \ \vdash :: P \in \mathrm{Ser} \,.\, Q \in \mathrm{D}^{\backprime}P\!\upharpoonright \,.\supset :.$

$$C^{\backprime}Q \in \mathrm{sect}^{\backprime}P \,.\equiv: (\exists R) \,.\, P = Q \updownarrow R \,.\vee.\, (\exists x) \,.\, P = Q \mapsto x :$$
$$\equiv : (\exists R) \,.\, P = Q \updownarrow R \,.\vee.\, P = Q \mapsto B^{\backprime}\breve{P}$$

That is, given any series contained in P, if something can be added to make it into P, its field is a section of P, and vice versa.

$*211{\cdot}01.\ \ \mathrm{sect}^{\backprime}P = \hat{\alpha}(\alpha \subset C^{\backprime}P \,.\, P^{\backprime\backprime}\alpha \subset \alpha)$ Df

$*211{\cdot}1.\ \ \vdash : \alpha \in \mathrm{sect}^{\backprime}P \,.\equiv.\, \alpha \subset C^{\backprime}P \,.\, P^{\backprime\backprime}\alpha \subset \alpha$ [(*211·01)]

$*211{\cdot}11.\ \ \vdash : \alpha \in \mathrm{D}^{\backprime}P_\epsilon \,.\equiv.\, (\exists\beta) \,.\, \alpha = P^{\backprime\backprime}\beta$ [*37·101]

$*211{\cdot}12.\ \ \vdash : \alpha \in \mathrm{D}^{\backprime}(P_\epsilon \dot{\cap} I) \,.\equiv.\, \alpha = P^{\backprime\backprime}\alpha$

Dem.

$\vdash . *37{\cdot}101 . *50{\cdot}1 . \supset \vdash : \alpha \in \mathrm{D}^{\backprime}(P_\epsilon \dot{\cap} I) \,.\equiv.\, (\exists\beta) \,.\, \alpha = P^{\backprime\backprime}\beta \,.\, \alpha = \beta \,.$

[*13·195] $\equiv .\, \alpha = P^{\backprime\backprime}\alpha : \supset \vdash .$ Prop

$*211{\cdot}13.\ \ \vdash : \alpha \in \mathrm{sect}^{\backprime}P \,.\equiv.\, \alpha = P_*{}^{\backprime\backprime}\alpha \,.\equiv.\, \alpha \in \mathrm{D}^{\backprime}\{(P_*)_\epsilon \dot{\cap} I\} \,.\equiv.\, \alpha \in \mathrm{D}^{\backprime}(P_*)_\epsilon$

The following propositions are concerned with $\mathrm{D}‘P_\epsilon$. This is to be compared with two other classes, namely $\mathrm{sect}‘P$ and $\overrightarrow{P}“C‘P$. The members of $\mathrm{sect}‘P$ which do not belong to $\mathrm{D}‘P_\epsilon$ are those which have a maximum but no sequent, *i.e.* (if P is a series), those classes which consist of a term x together with all its predecessors, where x has no immediate successor. In series in which every term except the last has an immediate successor, $C‘P$ will be the only member of $\mathrm{sect}‘P - \mathrm{D}‘P_\epsilon$, if the series has a last term; if the series has no last term, $\mathrm{sect}‘P = \mathrm{D}‘P_\epsilon$.

The members of $\mathrm{D}‘P_\epsilon$ which are not members of $\overrightarrow{P}“C‘P$ are those that have no sequent, *i.e.* those that have no upper limit (for a member of $\mathrm{D}‘P_\epsilon$ which has no sequent has also no maximum). These are the members of $\mathrm{D}‘P_\epsilon$ corresponding to a "gap," *i.e.* to a Dedekind section in which neither the earlier terms have a maximum nor the later terms a minimum. Hence in a Dedekindian series, $\mathrm{D}‘P_\epsilon = \overrightarrow{P}“C‘P$; and conversely, if $\mathrm{D}‘P_\epsilon = \overrightarrow{P}“C‘P$, the series is Dedekindian. These properties of $\mathrm{D}‘P_\epsilon$ are proved in the following propositions.

The above proposition and the two following propositions enable us in certain cases to prove propositions concerning the relations of $\text{sect}`P$ and $\text{D}`P_\epsilon$ without assuming that P is transitive. An example of the use of these propositions occurs in $*211{\cdot}754$, where the hypothesis assumes $P \epsilon \text{Rl}`J \cap \text{connex}$. If we used $*211{\cdot}31$ and its consequences instead of $*211{\cdot}314$ and its consequences, the hypothesis of $*211{\cdot}754$ would have to assume $P \epsilon \text{Ser}$.

The following propositions are concerned with $\mathrm{D}`(P_\epsilon \dot{\cap} I)$, *i.e.* with those sections of $P$ which have no maximum. If $P$ is compact (*i.e.* if $P^2 = P$), $\mathrm{D}`(P_\epsilon \dot{\cap} I) = \mathrm{D}`P_\epsilon$. If $P$ is also a Dedekindian series, $\mathrm{D}`(P_\epsilon \dot{\cap} I) = \overrightarrow{P}``C`P$. This is the mark of Dedekindian continuity, since it states that, if $P``\alpha$ has no maximum, there is an x for which $P``\alpha = \overrightarrow{P}`x$, and this $x$ is the upper limit of $P``\alpha$; while conversely, if x is any term of $C`P$, $\overrightarrow{P}`x$ has no maximum, so that the series is compact.

In the hypothesis of *211·61, it is necessary that P should be transitive as well as connected. Take, for example,

$$P = x \downarrow y \cup y \downarrow z \cup z \downarrow x \quad (x \neq y . x \neq z . y \neq z).$$

Then P is connected, but not transitive; also we have

$$\overrightarrow{P}`y = \iota`x . \overrightarrow{P}`z = \iota`y.$$

Hence $\qquad \iota`x, \iota`y \in \text{D}`P_\epsilon . \sim(\iota`x \subset \iota`y) . \sim(\iota`y \subset \iota`x).$

Thus connection is not sufficient in the hypothesis of *211·61.

$\exists ! \,\text{Cl}\,\text{ex}'C'P - \text{Cl}'\text{max}_P \,.\supset .\, \text{Hp}\,*210{\cdot}251$ [*211·691·661]

The following propositions are concerned with the relations of sections and segments of P to sections and segments of $\breve{P}$. When $\alpha \epsilon \text{sect}'P$, $C'P - \alpha \epsilon \text{sect}'\breve{P}$, and vice versa. Also, if P is connected, the maximum of α (if any) is the precedent with respect to P (*i.e.* the sequent with respect to $\breve{P}$) of $C'P - \alpha$, and the sequent of α (if any) is the minimum with respect to P (*i.e.* the maximum with respect to $\breve{P}$) of $C'P - \alpha$. Hence the relations to be proved follow easily.

The above hypothesis is not sufficient to secure $\overrightarrow{\text{seq}}_P{}'\alpha = \overrightarrow{\min}_P{}'(C'P - \alpha)$, as may be seen by putting

$$P = \alpha \uparrow (\alpha \cup \iota'x), \text{ where } \exists ! \alpha . x \sim\in \alpha.$$

We then have $P \in \text{connex} . P``\alpha = \alpha . C'P - \alpha = \iota'x . p'\overleftarrow{P}``\alpha = \alpha \cup \iota'x$. Thus $\overrightarrow{\min}_P{}'(C'P - \alpha) = \iota'x . \overrightarrow{\text{seq}}_P{}'\alpha = \Lambda$. It will be seen that $\alpha \uparrow (\alpha \cup \iota'x) \in \text{trans}$, so that it is useless to add $P \in \text{trans}$ to the hypothesis of *211·714. A sufficient addition is $P \subseteq J$, as is proved in the following proposition.

***211·715.** $\vdash : P \in \text{connex} \cap \text{Rl}'J . \alpha \in \text{sect}'P . \supset . \overrightarrow{\text{seq}}_P{}'\alpha = \overrightarrow{\min}_P{}'(C'P - \alpha)$

Dem.

The following propositions sum up our previous results.

***211·75.** $\vdash :. \alpha \subset C\text{‘}P \,.\, Q = \breve{P} \,.\supset: \alpha \in \text{sect}\text{‘}P \,.\equiv.\, C\text{‘}P - \alpha \in \text{sect}\text{‘}Q \quad [*211{\cdot}7]$

***211·751.** $\vdash :. P \in \text{Ser} \,.\, \alpha \subset C\text{‘}P \,.\, Q = \breve{P} \,.\supset:$

$$\alpha \in \mathrm{D}\text{‘}P_\epsilon \,.\equiv.\, C\text{‘}P - \alpha \in \text{sect}\text{‘}Q \cap (\text{ᗡ}\text{‘}\text{max}_Q \cup - \text{ᗡ}\text{‘}\text{seq}_Q)$$

Dem.

$\vdash . *211{\cdot}32 . \supset \vdash :. \text{Hp} . \supset : \alpha \in \mathrm{D}\text{‘}P_\epsilon \,.\equiv.\, \alpha \in \text{sect}\text{‘}P \cap (\text{ᗡ}\text{‘}\text{seq}_P \cup - \text{ᗡ}\text{‘}\text{max}_P) .$

$[*211{\cdot}75{\cdot}726] \qquad \equiv . C\text{‘}P - \alpha \in \text{sect}\text{‘}Q \cap (\text{ᗡ}\text{‘}\text{max}_Q \cup - \text{ᗡ}\text{‘}\text{seq}_Q) :. \supset \vdash . \text{Prop}$

In the above proposition, "$P \in \text{trans}$" is necessary in order that $\mathrm{D}\text{‘}P_\epsilon$ may be contained in $\text{sect}\text{‘}P$, and "$P \in \text{Rl}\text{‘}J$" is necessary in order that "$(C\text{‘}P - \alpha) \sim\in \text{ᗡ}\text{‘}\text{seq}_Q$" may imply "$\alpha \sim\in \text{ᗡ}\text{‘}\text{max}_P$." Hence the full hypothesis "$P \in \text{Ser}$" becomes necessary.

$*$212. THE SERIES OF SEGMENTS

Summary of $*$212.

The series of segments or sections of a series may be ordered by the relation of inclusion, after the manner considered in $*$210. Since, as was shown in $*$211, sections and segments have the properties assigned to κ in the hypothesis of $*$210, the resulting series are such that every class has either a maximum or a sequent, and either a minimum or a precedent; *i.e.* the series of segments or sections are Dedekindian. Most of the properties of the series of sections and of the series of segments which have no maximum, only require that the original relation should be connected. The properties of the series of segments in general ($\mathrm{D}`P_\epsilon$) require also that the original relation should be transitive.

We denote the series of segments by $\varsigma`P$, putting

$$\varsigma`P = P_{\mathrm{lc}} \upharpoonright \mathrm{D}`P_\epsilon \quad \mathrm{Df.}$$

We then have, in virtue of $*$210·13 and $*$211·61,

$*$**212·23.** $\vdash : P \epsilon \mathrm{trans} \cap \mathrm{connex} . \supset . \varsigma`P = \hat{\alpha}\hat{\beta}\{\alpha, \beta \epsilon \mathrm{D}`P_\epsilon . \alpha \subset \beta . \alpha \neq \beta\}$

In like manner, for the series of segments which have no maximum, we put

$$\mathrm{sgm}`P = P_{\mathrm{lc}} \upharpoonright \mathrm{D}`(P_\epsilon \dot{\cap} I) \quad \mathrm{Df,}$$

and we have

$*$**212·22.** $\vdash : P \epsilon \mathrm{connex} . \supset . \mathrm{sgm}`P = \hat{\alpha}\hat{\beta}\{\alpha, \beta \epsilon \mathrm{D}`(P_\epsilon \dot{\cap} I) . \alpha \subset \beta . \alpha \neq \beta\}$

We do not need a special notation for the series of sections, since, in virtue of $*$211·13, it is $\varsigma`P_*$ or $\mathrm{sgm}`P_*$. Thus, by $*$212·23,

$*$**212·24.** $\vdash : P_* \epsilon \mathrm{connex} . \supset . \varsigma`P_* = \hat{\alpha}\hat{\beta}\{\alpha, \beta \epsilon \mathrm{sect}`P . \alpha \subset \beta . \alpha \neq \beta\}$

We begin the number with various propositions on the fields, etc. of these relations, and on the conditions for their existence. We have

$*$**212·132.** $\vdash . \mathrm{D}`\varsigma`P = \mathrm{D}`P_\epsilon - \iota`\mathrm{D}`P . \mathrm{G}`\varsigma`P = \mathrm{D}`P_\epsilon - \iota`\Lambda$

$*$**212·133.** $\vdash : \dot{\exists} ! P . \supset . C`\varsigma`P = \mathrm{D}`P_\epsilon . B`\varsigma`P = \Lambda . B`\mathrm{Cnv}`\varsigma`P = \mathrm{D}`P$

$*$**212·14.** $\vdash : \dot{\exists} ! P . \equiv . \dot{\exists} ! \varsigma`P$

$*$**212·152.** $\vdash . \mathrm{G}`\mathrm{sgm}`P = \mathrm{D}`(P_\epsilon \dot{\cap} I) - \iota`\Lambda$

$*$**212·17.** $\vdash : \dot{\exists} ! \varsigma`P_* . \equiv . \exists ! \mathrm{sect}`P - \iota`\Lambda . \equiv . \mathrm{sect}`P \sim\epsilon 1 . \equiv . \dot{\exists} ! P$

$*$**212·172.** $\vdash : \dot{\exists} ! P . \supset . C`\varsigma`P_* = \mathrm{sect}`P . B`\varsigma`P_* = \Lambda . B`\mathrm{Cnv}`\varsigma`P_* = C`P$

Of the next set of propositions ($*$212·2—·25), several have already been mentioned. An important proposition is

$*$**212·25.** $\vdash : P \epsilon \mathrm{Ser} . \supset . \overrightarrow{P} ; P = (\varsigma`P) \upharpoonright \overrightarrow{P}``C`P$

for this shows that the series of segments contains a series similar to P.

We take up next the application of the propositions of $*210$ to the series of sections and segments. We show that if $P \epsilon \text{connex}$, $\text{sgm}`P$ and $\varsigma`P_*$ are series ($*212{\cdot}3$), and that if P is also transitive, $\varsigma`P$ is a series ($*212{\cdot}31$). We have

$*212{\cdot}322$. $\vdash : P \epsilon \text{connex} . \dot{\exists} ! P . \lambda \subset \text{sect}`P . \supset . s`\lambda = \text{limax}(\varsigma`P_*)`\lambda$

$*212{\cdot}34$. $\vdash : P \epsilon \text{connex} . \dot{\exists} ! P . \lambda \subset \text{sect}`P . \supset . p`\lambda \cap C`P = \text{limin}(\varsigma`P_*)`\lambda$

so that every class of sections has both an upper limit or maximum and a lower limit or minimum ($*212{\cdot}35$).

We then prove similar propositions for $\varsigma`P$ and $\text{sgm}`P$, except that in place of $*212{\cdot}34$ we have

$*212{\cdot}431$. $\vdash : P \epsilon \text{trans} \cap \text{connex} . \dot{\exists} ! P . \lambda \subset \text{D}`P_\epsilon . \supset .$
$$s`(\text{D}`P_\epsilon \cap \text{Cl}`p`\lambda) = \text{limin}(\varsigma`P)`\lambda$$

$*212{\cdot}53$. $\vdash : P \epsilon \text{connex} . \dot{\exists} ! \text{sgm}`P . \lambda \subset \text{D}`(P_\epsilon \dot{\cap} I) . \supset .$
$$s`\{\text{D}`(P_\epsilon \dot{\cap} I) \cap \text{Cl}`p`\lambda\} = \text{limin}(\text{sgm}`P)`\lambda$$

The reason of the difference from $*212{\cdot}34$ is that the product of an existent class of segments may not be a segment. Suppose, for example, the segments are all those that contain a given term x, where x has no immediate successor; then their logical product is $\overrightarrow{P}`x \cup \iota`x$, which is a section but not a segment.

We have next ($*212{\cdot}6$—$\cdot667$) a number of propositions on the limits and maxima of sub-classes of $\overrightarrow{P}``C`P$ in the series $\varsigma`P$. The interest of this subject lies in its relation to irrationals. If $\alpha$ is a class contained in $C`P$ and having no limit or maximum, $\overrightarrow{P}``\alpha$ is contained in $C`\varsigma`P$, and has a limit in $\varsigma`P$. We may call this limit an *irrational* segment. There is no irrational term in $C`P$, because in P there is no limit to α; but the limit, in $\varsigma`P$, of $\overrightarrow{P}``\alpha$ may be called irrational, because it corresponds to no term in $C`P$. It should be observed that (as will be proved in Section F) if $P$ is similar to the series of rationals, $\varsigma`P$ is similar to the series of real numbers.

The most useful propositions in this subject are:

$*212{\cdot}6$. $\vdash : P \epsilon \text{Ser} . \alpha \subset C`P . \supset .$
$$\overrightarrow{\max}(\varsigma`P)`\overrightarrow{P}``\alpha = \overrightarrow{\max}(\overrightarrow{P} ; P)`\overrightarrow{P}``\alpha = \overrightarrow{P}``\overrightarrow{\max}_P`\alpha$$

$*212{\cdot}601$. $\vdash :. P \epsilon \text{Ser} . \alpha \subset C`P . \supset :$
$$\text{E} ! \max_P`\alpha . \equiv . \text{E} ! \max(\overrightarrow{P} ; P)`\overrightarrow{P}``\alpha . \equiv . \text{E} ! \max(\varsigma`P)`\overrightarrow{P}``\alpha$$

$*212{\cdot}602$. $\vdash :. P \epsilon \text{Ser} . \dot{\exists} ! P . \alpha \subset C`P . \supset : \text{E} ! \max_P`\alpha . \equiv . P``\alpha \epsilon \overrightarrow{P}``\alpha$

$*212{\cdot}61$. $\vdash : P \epsilon \text{trans} \cap \text{connex} . \dot{\exists} ! P . \supset . \text{limax}(\varsigma`P)`\overrightarrow{P}``\alpha = P``\alpha$

$*212{\cdot}632$. $\vdash : P \epsilon \text{Ser} . \dot{\exists} ! P . \alpha \subset C`P . P``\alpha \sim \epsilon \overrightarrow{P}``C`P . \supset . P``\alpha = \text{lt}(\varsigma`P)`\overrightarrow{P}``\alpha$

***212·661.** $\vdash : P \in \mathrm{Ser} \,.\, \kappa \subset \mathrm{D}`P_\epsilon \,.\, \mathrm{E}\,!\,\mathrm{lt}(\varsigma`P)`\kappa \,.\, \supset \,.$

$$\mathrm{lt}(\varsigma`P)`\kappa = \mathrm{lt}(\varsigma`P)`\overrightarrow{P}``s`\kappa = s`\kappa$$

This shows that every limit in the series of segments is a limit of a class of what we may call *rational* segments (*i.e.* segments of the form $\overrightarrow{P}`x$), namely it is the limit of $\overrightarrow{P}``s`\kappa$.

***212·667.** $\vdash : P \in \mathrm{Ser} \,.\, \supset \,.\, \mathrm{D}`\mathrm{lt}(\varsigma`P) - \iota`\Lambda = \text{Cl}`\mathrm{sgm}`P$

This shows that the segments (other than Λ) which are limits of classes of segments are the segments (other than Λ) which have no maximum in P.

The number ends with a set of propositions (*212·7—·72) on the relations of the sections and segments of two correlated series. If S is a correlator of P with Q, then S_ϵ (with its converse domain limited) is a correlator of $\varsigma`P_*$ with $\varsigma`Q_*$, $\varsigma`P$ with $\varsigma`Q$ and $\mathrm{sgm}`P$ with $\mathrm{sgm}`Q$ (*212·71·711·712). Hence

***212·72.** $\vdash : P \,\mathrm{smor}\, Q \,.\, \supset \,.\, \varsigma`P_* \,\mathrm{smor}\, \varsigma`Q_* \,.\, \varsigma`P \,\mathrm{smor}\, \varsigma`Q \,.\, \mathrm{sgm}`P \,\mathrm{smor}\, \mathrm{sgm}`Q$

This proposition is used in the next number, and also in *271.

***212·01.** $\varsigma`P = P_{1c} \upharpoonright \mathrm{D}`P_\epsilon$ Df

***212·02.** $\mathrm{sgm}`P = P_{1c} \upharpoonright \mathrm{D}`(P_\epsilon \dot{\frown} I)$ Df

***212·1.** $\vdash : \alpha(\varsigma`P)\beta \,.\equiv .\, \alpha, \beta \in \mathrm{D}`P_\epsilon \,.\, \exists\,!\,\beta - \alpha - P``(\alpha - \beta)$
[*170·102 . *37·15]

***212·11.** $\vdash : \alpha(\mathrm{sgm}`P)\beta \,.\equiv .\, \alpha, \beta \in \mathrm{D}`(P_\epsilon \dot{\frown} I) \,.\, \exists\,!\,\beta - \alpha$

Dem.

$\vdash .\, *170·102 \,.\, *37·15 \,.\, \supset$

$\vdash : \alpha(\mathrm{sgm}`P)\beta \,.\equiv .\, \alpha, \beta \in \mathrm{D}`(P_\epsilon \dot{\frown} I) \,.\, \exists\,!\,\beta - \alpha - P``(\alpha - \beta)$ (1)

$\vdash .\, *211·12 \,.\, \supset \vdash : \alpha \in \mathrm{D}`(P_\epsilon \dot{\frown} I) \,.\, \supset \,.\, -\alpha = -P``\alpha \,.$

[*37·2.Transp] $\supset \,.\, -\alpha \subset -P``(\alpha - \beta) \,.$

[*22·621] $\supset \,.\, -\alpha - P``(\alpha - \beta) = -\alpha$ (2)

$\vdash .\, (1) \,.\, (2) \,.\, \supset \vdash .\, \mathrm{Prop}$

***212·12.** $\vdash : \alpha(\mathrm{sgm}`P_*)\beta \,.\equiv .\, \alpha, \beta \in \mathrm{sect}`P \,.\, \exists\,!\,\beta - \alpha$ [*211·13 . *212·11]

Thus $\mathrm{sgm}`P_*$ has the same connection with $\mathrm{sect}`P$ as $\mathrm{sgm}`P$ has with $\mathrm{D}`(P_\epsilon \dot{\frown} I)$. When P is transitive, $\mathrm{sgm}`P_*$ also has the same connection with $\mathrm{sect}`P$ as $\varsigma`P$ has with $\mathrm{D}`P_\epsilon$. The following proposition makes these facts more explicit.

The following propositions, down to *212·55, consist of applications of the propositions of *210, where the κ of that number is replaced by sect‘P, D‘P_ϵ, or D‘$(P_\epsilon \dot{\cap} I)$, and the Q is replaced by $P_{1c} \upharpoonright \kappa$, *i.e.* by ς‘P_*, ς‘P, or sgm‘P. The propositions which follow are important, since the use of segments, especially in connection with continuity, depends largely upon them.

***212·3.** $\vdash : P \in \mathrm{connex} . \supset . \mathrm{sgm}\text{‘}P, \varsigma\text{‘}P_* \in \mathrm{Ser}$

The proof proceeds as in *212·431.

***212·54.** $\vdash : P \in \text{connex} \,.\, \dot{\exists} \,!\, \text{sgm'}P \,.\, \supset .$

$(\lambda) \,.\, \lambda \in \{\text{ᗡ}\text{'max}\,(\text{sgm'}P) \cup \text{ᗡ}\text{'seq}\,(\text{sgm'}P)\} \cap \{\text{ᗡ}\text{'min}\,(\text{sgm'}P) \cup \text{ᗡ}\text{'prec}\,(\text{sgm'}P)\}$

***212·55.** $\vdash :. P \in \text{connex} \,.\, \supset : \lambda \in C\text{'sgm'sgm'}P \,.\, \supset .\, \text{E} \,!\, \text{seq}\,(\text{sgm'}P)\text{'}\lambda$

The following propositions are concerned with the relations of maxima, limits and sequents in P and $\varsigma\text{'}P$ respectively. The series $\overrightarrow{P};P$, which is ordinally similar to P, is contained in $\varsigma\text{'}P$; and if α has a maximum or limit in P, the maximum or limit of $\overrightarrow{P}\text{''}\alpha$ in $\varsigma\text{'}P$ is $\overrightarrow{P}\text{'max}_P\text{'}\alpha$ or $\overrightarrow{P}\text{'lt}_P\text{'}\alpha$.

In this way, a series (namely $\overrightarrow{P};P$) which has the same ordinal properties as P can be placed in a certain Dedekindian series (namely $\varsigma`P$) in such a way that the classes which have limits in P are those whose correlates have limits which are members of $\overrightarrow{P}``C`P$, while those whose correlates have limits which are not members of $\overrightarrow{P}``C`P$ are those which have neither a maximum nor a limit in $P$. These relations are important in many connections. For example, if $P$ is of the type of the rationals, $\varsigma`P$ is of the type of the real numbers: $C`\varsigma`P - \overrightarrow{P}``C`P$ corresponds to the irrationals, and classes contained in $\overrightarrow{P}``C`P$ but having a limit not belonging to $\overrightarrow{P}``C`P$ correspond to series of rationals having an irrational limit. In the original series $P$, there are no irrational limits; but if $\alpha$ is a class in $C`P$ and having no limit, $\overrightarrow{P}``\alpha$ has an irrational limit in $\varsigma`P$.

$*213$. SECTIONAL RELATIONS

Summary of $*213$.

If α is a section of P, $P \upharpoonright \alpha$ is called a *sectional relation* of P; and if α is a segment of P, $P \upharpoonright \alpha$ is called a *segmental relation* of P. If P_{po} is serial, sectional relations may be arranged in a series by the relation of inclusion ($*213\cdot153$). That is, if we call the series of sectional relations P_s, we shall so define P_s as to secure that if P_{po} is serial,

$$QP_sR \,.\equiv.\, Q, R \in P\upharpoonright``(\text{sect}`P - \iota`\Lambda) \,.\, Q \subseteq R \,.\, Q \neq R \quad (*213\cdot21).$$

The natural definition to take would be

$$P_s = P\upharpoonright ; \varsigma`P_*.$$

But this has the disadvantage that if xBP,

$$P\upharpoonright \iota`x = P\upharpoonright \Lambda \,.\, \Lambda, \iota`x \in \text{sect}`P.$$

Thus $P\upharpoonright \alpha = P\upharpoonright \beta$ does not imply $\alpha = \beta$; and when P is serial, $P\upharpoonright ; \varsigma`P_*$ is not serial, because $\dot\Lambda\,(P\upharpoonright ; \varsigma`P_*)\,\dot\Lambda$. In order to obviate this inconvenience, we confine ourselves to sections which are not null, putting

$$P_s = P\upharpoonright ; (\varsigma`P_*)\upharpoonright(-\iota`\Lambda) \quad \text{Df.}$$

With the above definition, we have ($*213\cdot151\cdot152$), if $P_{po} \in \text{Ser}$,

$$(P\upharpoonright) \upharpoonright C`\{(\varsigma`P_*)\upharpoonright - \iota`\Lambda\} \in 1 \to 1$$

and $$P_s \,\text{smor}\, (\varsigma`P_*)\upharpoonright(-\iota`\Lambda).$$

The relation P_s is very useful in dealing with well-ordered series; in this case, we have (as will be shown later)

$$P_s = P\upharpoonright ; \overrightarrow{P} ; P\upharpoonright \text{Cl}`P \dotplus\!\!\to P.$$

It will be seen that, if $P_{po} \in \text{Ser}$, whenever P exists, $P = B`\breve{P}_s$ ($*213\cdot158$); and whenever $\overrightarrow{B}`P$ exists, $\dot\Lambda = B`P_s$ ($*213\cdot155$).

We have, if $P_{po} \in \text{Ser}$,

$$QP_sR \,.\equiv.\, R \in C`P_s \,.\, Q \in \text{D}`R_s \quad (*213\cdot245).$$

Hence $\quad R \in C`P_s \,.\supset.\, \overrightarrow{P_s}`R = \text{D}`R_s \,.\, R_s = P_s \upharpoonright C`R_s \quad (*213\cdot246\cdot242)$.

If P is serial, the sectional relations of P are all relations such that by adding something to them they become P, *i.e.* they are

$$\hat{Q}\{(\exists R) \,.\, P = Q \,\text{\textcircled{+}}\, R \,.\vee.\, (\exists x) \,.\, P = Q \dotplus\!\!\to x\} \quad (*213\cdot4).$$

Hence their relation-numbers are those that can be made equal to that of P by being added to. This fact is important in connection with the theory of greater and less among relation-numbers.

The propositions of this number are rendered complicated by the necessity of taking account of the possibility of a section being a unit class. This

necessitates a good many propositions which are merely lemmas; but in the end the complications mostly disappear.

We begin with propositions on the field, etc., of P_s. We have

$*213\cdot141.\ \vdash . \mathrm{D}`P_s = P\upharpoonright``(\mathrm{sect}`P - \iota`\Lambda - \iota`C`P)$

$*213\cdot142.\ \vdash : P_{\mathrm{po}} \subseteq J . \supset . C`P_s = P\upharpoonright``(\mathrm{sect}`P - \iota`\Lambda)$

$*213\cdot16.\ \vdash . \mathrm{D}`P_s = P\upharpoonright``(\mathrm{sect}`P - \iota`\Lambda) - \iota`P$

$*213\cdot161.\ \vdash : P_{\mathrm{po}} \subseteq J . \exists ! \overrightarrow{B}`P . \supset . P\upharpoonright``\mathrm{sect}`P = P\upharpoonright``(\mathrm{sect}`P - \iota`\Lambda) = C`P_s$

$*213\cdot162.\ \vdash : P_{\mathrm{po}} \in \mathrm{Ser} . \supset . \mathrm{G}`P_s = P\upharpoonright``\mathrm{sect}`P - \iota`\dot{\Lambda}$

We then prove:

$*213\cdot17.\ \vdash : P_{\mathrm{po}} \in \mathrm{Ser} . \supset . \mathrm{Nr}`\varsigma`P_* = \dot{1} \dotplus \mathrm{Nr}`P_s .$
$\mathrm{Nr}`(\varsigma`P_*)\upharpoonright(\mathrm{G}`\varsigma`P_*) = \mathrm{Nr}`P_s$

If P is finite, it follows from the above that $\varsigma`P_*$ is not similar to P_s; but if P is infinite and has a beginning and is well-ordered, we find

$$\mathrm{Nr}`\varsigma`P_* = \mathrm{Nr}`P_s .$$

$*213\cdot172.\ \vdash : P_{\mathrm{po}}, Q_{\mathrm{po}} \in \mathrm{Ser} . P \,\mathrm{smor}\, Q . \supset . P_s \,\mathrm{smor}\, Q_s$

We then have a set of propositions ($*213\cdot2$—$\cdot251$) chiefly concerned with the sections of R, where $R \in C`P_s$. Besides those already mentioned, the following are important:

$*213\cdot24.\ \vdash : \beta \in \mathrm{sect}`P . R = P\upharpoonright\beta . \supset . \mathrm{sect}`R = \mathrm{sect}`P \cap \mathrm{Cl}`C`R$

$*213\cdot243.\ \vdash . \overrightarrow{P_s}`P = \mathrm{D}`P_s$

$*213\cdot25.\ \vdash :. P_{\mathrm{po}} \in \mathrm{Ser} . Q, R \in C`P_s . \supset : Q \in \mathrm{D}`R_s . \vee . R \in \mathrm{D}`Q_s . \vee . Q = R$

Our next set ($*213\cdot3$—$\cdot32$) is concerned with $\dot{\Lambda}$ and $x \downarrow y$. We have

$*213\cdot3.\ \vdash : P = \dot{\Lambda} . \supset . P_s = \dot{\Lambda}$

$*213\cdot32.\ \vdash : P \in 2_r . \supset . P_s = \dot{\Lambda} \downarrow P . P_s \in 2_r$

We then have three propositions ($*213\cdot4\cdot41\cdot42$) showing that a sectional relation of P is one which becomes P by being added to. We proceed to a set of propositions ($*213\cdot5$—$\cdot58$) on $(P \rightarrow\!\!\!+ x)_s$ and $(P \,\dot{+}\, Q)_s$, leading to

The hypothesis $P_{po} \in J$, in the above proposition, restricts P more than is necessary for the truth of the conclusion. What we really require is $P = \dot{\Lambda} . \mathbf{v} . (\exists x) . x \epsilon C'P . \overrightarrow{P_*}'x \neq C'P$, *i.e.* $\overrightarrow{P_*}``C'P \neq \iota'C'P$. This holds if either (1) the field of $P$ does not consist of a single family, or (2) there is a member of $C'P$ which does not have the relation $P_{po}$ to itself. Thus the only case excluded is that of a single cyclic family. The hypothesis $\overrightarrow{P_*}``C'P \neq \iota'C'P$ may be substituted for $P_{po} \in J$ in most of the subsequent propositions of this number in which $P_{po} \in J$ occurs in the hypothesis. We have, however, preferred the hypothesis $P_{po} \in J$, as it gives a more immediate application to the case of $P \epsilon \mathrm{Ser}$, which is the case in which the propositions of the present number are important.

$*214$. DEDEKINDIAN RELATIONS

Summary of $*214$.

We call a relation "Dedekindian" when it is such that every class has either a maximum or a sequent with respect to it. As a rule, the hypothesis that a relation is Dedekindian is only important in the case of serial relations. Dedekindian series have considerable importance, especially in connection with limits.

When P is transitive, the hypothesis that P is Dedekindian is equivalent to the hypothesis that every section of P has a maximum or a sequent ($*214\cdot13$); it is also equivalent to the assumption that every segment of P has a maximum or a sequent ($*214\cdot131$), *i.e.* to the assumption that every segment of P which has no maximum has a limit, *i.e.* to

$$\text{D}`(P_\epsilon \dot{\cap} I) \subset \text{Ɑ}`\text{lt}_P.$$

When P is a series, the hypothesis that it is Dedekindian is equivalent to the hypothesis that every segment has a sequent ($*214\cdot15$), *i.e.* to the hypothesis that the class of segments is the class $\overrightarrow{P}``C`P$ ($*214\cdot151$). If $P$ is a Dedekindian series, so is $\breve{P}$, and vice versa ($*214\cdot14$). Whenever $P$ is connected and not null, $s`P_*$ is a Dedekindian series ($*214\cdot32$), and so is $\text{sgm}`P$ if it exists ($*214\cdot34$); whenever $P$ is transitive and connected and not null, $s`P$ is a Dedekindian series ($*214\cdot33$). All these propositions have been virtually proved already: almost the only thing new in the present number is the definition, which is

$$\text{Ded} = \hat{P}\{(\alpha) . \alpha \in \text{Ɑ}`\text{max}_P \cup \text{Ɑ}`\text{seq}_P\} \quad \text{Df.}$$

$*214\cdot4$—$\cdot43$ give properties of series which have Dedekindian continuity. We have

$*214\cdot4$. $\vdash :. P^2 = P . P \in \text{connex} . \supset : P \in \text{Ded} . \equiv . \text{Ɑ}`\text{max}_P = - \text{Ɑ}`\text{seq}_P$

$*214\cdot41$. $\vdash :. P \in \text{Ser} . \supset : P^2 = P . P \in \text{Ded} . \equiv . \text{Ɑ}`\text{max}_P = - \text{Ɑ}`\text{seq}_P$

I.e. in a series, Dedekindian continuity is equivalent to the assumption that the classes which have a maximum are the same as the classes which have no sequent.

$*214\cdot42$. $\vdash : P \in \text{Ser} \cap \text{Ded} . P^2 = P . \alpha \in \text{sect}`P . \supset . \text{limax}_P`\alpha = \text{limin}_P`(C`P - \alpha)$

This proposition is important in dealing with Dedekind "cuts."

$*214\cdot43$. $\vdash :. P \in \text{Ser} \cap \text{Ded} . \alpha \in \text{sect}`P . \supset :$

$$\text{limax}_P`\alpha = \text{limin}_P`(C`P - \alpha) . \vee . \text{max}_P`\alpha \, P_1 \, \text{min}_P`(C`P - \alpha)$$

$*214\cdot5$ shows that a Dedekindian relation has a beginning and an end; the following propositions deal with $P \dot{\cap} J$ when P is Dedekindian.

$*214\cdot6$ shows that a relation which is similar to a Dedekindian relation is Dedekindian.

We call a relation "semi-Dedekindian" if it becomes Dedekindian by the addition of one term at the end; the definition is

$*214\cdot02$. semi Ded $= \hat{P}\,(\text{sect}`P - \iota`C`P \subset \text{Cl}`\text{max}_P \cup \text{Cl}`\text{seq}_P)$ Df

---

$*214\cdot01$. Ded $= \hat{P}\,\{(\alpha) . \alpha \in \text{Cl}`\text{max}_P \cup \text{Cl}`\text{seq}_P\}$ Df

*215. STRETCHES

Summary of *215.

A *stretch* of a series is any piece taken out of it, and not having any gaps; that is, it is a class contained in the series, and containing all terms which come between any two of its terms. Thus it is defined as

$$\hat{\alpha}(\alpha \subset C`P \,.\, P``\alpha \cap \breve{P}``\alpha \subset \alpha).$$

We denote the class of stretches by "str$`P$," where "str" stands for "stretch" or "Strecke." A stretch which has no predecessors is a section of P; one which has no successors is a section of $\breve{P}$. The properties of stretches are chiefly important in connection with compact series. In discrete series, stretches are the same as intervals.

If P is transitive, stretches of P are the products of sections of P and sections of $\breve{P}$, *i.e.* of upper and lower sections of P (*215·16). If P is connected, and α is a lower section, β an upper section, then if the two have a stretch $\alpha \cap \beta$ in common, we have

$$\alpha = P``(\alpha \cap \beta) \cup (\alpha \cap \beta) \,.\, \beta = \breve{P}``(\alpha \cap \beta) \cup (\alpha \cap \beta) \quad (*215·161).$$

A slightly more general form of this proposition is

***215·165.** $\vdash : P_{po} \in \text{connex} \,.\, \alpha \in \text{sect}`P \,.\, \beta \in \text{sect}`\breve{P} \,.\, \exists ! \alpha \cap \beta \,.\, \supset .$

$$\alpha = P_*``(\alpha \cap \beta) \,.\, \beta = \breve{P}_*``(\alpha \cap \beta) \,.\, P``\alpha = P_{po}``(\alpha \cap \beta) \,.\, \breve{P}``\beta = \breve{P}_{po}``(\alpha \cap \beta)$$

A specially important case is when α and β have just one term in common. In this case we have

***215·166.** $\vdash : P_{po} \in \text{Ser} \,.\, \alpha \in \text{sect}`P \,.\, \beta \in \text{sect}`\breve{P} \,.\, \alpha \cap \beta \in 1 \,.\, \supset .$

$$\alpha \cap \beta = \iota`\text{max}_P`\alpha = \iota`\text{min}_P`\beta$$

When $\alpha \cap \beta$ has more than one term, if the upper limit or maximum of α and the lower limit or minimum of β both exist, the latter precedes the former (*215·52); if α and β have no common part, but together exhaust the field of P, we have either $\text{limax}_P`\alpha = \text{limin}_P`\beta$ or $\text{limax}_P`\alpha P_1 \text{limin}_P`\beta$, assuming $E ! \text{limax}_P`\alpha \,.\, E ! \text{limin}_P`\beta$ (*215·54). Hence if $\text{limax}_P`\alpha$ has no immediate successor, it must be identical with $\text{limin}_P`\beta$. Thus we have

***215·543.** $\vdash : P \in \text{Ser} \,.\, \alpha \in \text{sect}`P \,.\, \beta \in \text{sect}`\breve{P} \,.\, \alpha \cup \beta = C`P \,.\, \alpha \cap \beta \in 0 \cup 1 \,.$

$$E ! \text{limax}_P`\alpha \,.\, \text{limax}_P`\alpha \sim\in D`P_1 \,.\, \supset .\, \text{limax}_P`\alpha = \text{limin}_P`\beta$$

The above propositions will be useful in Section C (*231 and *233).

$*216$. DERIVATIVES

Summary of $*216$.

If α is any class, and P is any series, the *derivative* (or *first derivative*) of α with respect to P is the class of limits of existent sub-classes of $\alpha \cap C'P$, *i.e.* $\mathrm{lt}_P``\mathrm{Cl\,ex}`(\alpha \cap C`P)$. That is, a term x belongs to the derivative of α if a set of terms exists which is contained both in α and in $C`P$, and has $x$ for its limit. The derivative of $\alpha$ with respect to $P$ will be denoted by $\delta_P`\alpha$.

In general, there will be members of α not contained in $\delta_P`\alpha$, and members of $\delta_P`\alpha$ not contained in α. α is said to be *dense* in P if all its terms except the first (if there is a first) belong to $\delta_P`\alpha$, that is, if all its terms except the first are limits of existent classes contained in α. α is said to be *closed* in P if every existent sub-class of α which has no maximum has a limit which belongs to α, *i.e.* if every existent sub-class of α has a limit or a maximum, and the derivative of α is contained in α. If α is both dense and closed, it is called *perfect*. In this case, all its terms are limits of classes chosen out of α, and every class chosen out of α has a limit or maximum in α.

The second derivative of α is $\delta_P`\delta_P`\alpha$, *i.e.* $\delta_P{}^2`\alpha$, and so on. (Derivatives of infinite order cannot be dealt with till a later stage.) If P is serial, the second derivative of α is always contained in the first ($*216{\cdot}14$).

If P is a Dedekindian series, α is closed whenever $\delta_P`\alpha \subset \alpha$. In order to secure a Dedekindian series, it is sometimes convenient to replace $P$ by the ordinally similar series $\overrightarrow{P};P$, which is contained in the Dedekindian series $\varsigma`P$. Then α is replaced by $\overrightarrow{P}``\alpha$, and $\alpha$ is closed if the derivative of $\overrightarrow{P}``\alpha$ with respect to $\varsigma`P$ is contained in $\overrightarrow{P}``\alpha$. The relation of the derivative of $\alpha$ in $P$ to the derivative of $\overrightarrow{P}``\alpha$ in $\varsigma`P$ has been treated in $*212{\cdot}6$ and following propositions. This subject is resumed below ($*216{\cdot}5$ ff.).

The derivative of the series P will be defined as the series of its limit-points, and denoted by $\nabla`P$. Thus we put

$$\nabla`P = P \upharpoonright \mathrm{D}`\mathrm{lt}_P.$$

If P is a series, the derivative of a class α consists of those members x of $\mathrm{C\!\!\!I}`P$ which are such that members of α exist in every interval which ends in x, *i.e.*

$*216{\cdot}13$. $\vdash :: P \in \mathrm{Ser} . \supset :. x \in \delta_P`\alpha . \equiv : x \in \mathrm{C\!\!\!I}`P : yPx . \supset_y . \exists ! \alpha \cap \overleftarrow{P}`y \cap \overrightarrow{P}`x$

We have

$*216{\cdot}2$. $\vdash . \delta_P`C`P = \mathrm{D}`\mathrm{lt}_P - \overrightarrow{B}`P$

$*216{\cdot}3$. $\vdash : \alpha \in \mathrm{dense}`P . \equiv . \alpha - \overrightarrow{\min}_P`\alpha \subset \delta_P`\alpha$

***216·32.** $\vdash : \alpha \epsilon \text{closed}'P . \equiv . \text{Cl ex}'(\alpha \cap C'P) \subset \text{Ɑ}'\text{limax}_P . \delta_P'\alpha \subset \alpha$

We prove (*216·4—·412) that the properties of α with respect to P, as regards being dense, closed, or perfect, belong to $\breve{S}``\alpha$ with respect to Q if S is a correlator of P with Q.

We next consider the relation of α in P to $\overrightarrow{P}``\alpha$ in $\varsigma'P$ (*216·5—·56). The point of these propositions is that $\varsigma'P$ is Dedekindian, so that a class is closed in $\varsigma'P$ if it contains its first derivative. (It is usual to *define* a class as closed whenever it contains its first derivative; but this involves the tacit assumption that the series P is Dedekindian. If P is the series of real numbers, this assumption is of course verified.) We prove (*216·52) that the derivative of $\overrightarrow{P}``\alpha$ in $\varsigma'P$ is $P```(\text{Cl ex}'\alpha - \text{Ɑ}'\text{max}_P)$, *i.e.* is the class of segments defined by such existent sub-classes of α as have no maximum; we show that α is dense, closed, or perfect in P according as $\overrightarrow{P}``\alpha$ is dense, closed, or perfect in $\varsigma'P$ (*216·53·54·56), and that $\alpha$ and $\overrightarrow{P}``\alpha$ are closed if $\overrightarrow{P}``\alpha$ contains its first derivative (*216·54).

We end with various propositions on $\nabla'P$ (*216·6—·621), of which the chief is

***216·611.** $\vdash : P \epsilon \text{Ser} . \dot{\exists} ! \nabla'P . \supset . C'\nabla'P = C'P - \text{Ɑ}'P_1 = \delta_P'C'P \cup \overrightarrow{B}'P$

This subject will be resumed in connection with well-ordered series in *264.

*217. ON SEGMENTS OF SUMS AND CONVERSES

Summary of *217.

The purpose of the present number is to prove *217·43, which is required in the theory of real numbers (Part VI, Section A), where Q will be the series of positive ratios including zero, P will be the series of negative ratios in the order from zero to $-\infty$ (both excluded), α the real number zero, and Z and W two different series either of which may be taken as the series of negative and positive real numbers. In virtue of *217·43, these two series are ordinally similar.

SECTION C

ON CONVERGENCE, AND THE LIMITS OF FUNCTIONS

Summary of Section C.

The purpose of this section is to express in a general form the definitions of convergence, the limits of functions, the continuity of functions, and kindred notions, and to give such elementary consequences of these definitions as may seem illustrative.

In the definitions usually given in treatises on analysis, it is assumed that both the arguments and the values of the function are numbers of some kind, generally real numbers, and limits are taken with respect to the order of magnitude. There is, however, nothing essential in the definitions to demand so narrow a hypothesis. What is essential is that the arguments should be given as belonging to a series, and that the values should also be given as belonging to a series, which need not be the same series as that to which the arguments belong. In what follows, therefore, we assume that all the possible arguments to our function, or at any rate all the arguments which we consider, belong to the field of a certain relation Q, which, in cases where our definitions are useful, will be a serial relation; we assume similarly that the values of our function, at least for arguments belonging to $C‘Q$, belong to the field of a relation P, which, in all important cases, will be a serial relation. The function itself we represent by the relation of the value to the argument; that is, the relation of $f(x)$ to x is to be R, so that, if the function is one-valued, $f(x) = R‘x$. (If the function is not one-valued, $f(x)$ is any member of $\overrightarrow{R}‘x$.) Thus we may speak of R as the function, Q as the argument-series, and P as the value-series.

To take an illustration: Suppose we are given a set of real numbers $x_1, x_2, \ldots x_\nu, \ldots$, where ν may be any finite integer. Here x_ν is a function of ν; the argument-series is that of the finite integers in order of magnitude, the value-series is that of the real numbers (or any part of this series which contains all the values $x_1, x_2, \ldots x_\nu, \ldots$). The function R is the relation of x_ν to ν, so that $x_\nu = R‘\nu$. In this case, calling the argument-series Q and the value-series P (as will be done throughout this section), we have $\text{Ɑ}‘R = C‘Q =$ the finite integers, $R``C‘Q = \text{D}‘R =$ the *class* $x_1, x_2, \ldots x_\nu, \ldots$, and $R;Q =$ the *series* $x_1, x_2, \ldots x_\nu, \ldots$. The series which arranges $x_1, x_2, \ldots x_\nu, \ldots$ in the order of their own magnitudes, instead of the order of magnitude of their suffixes, is $P \upharpoonright \text{D}‘R$ or $P \upharpoonright R``C‘Q$. This will not be equal to $R;Q$ unless the function is one which continually increases, *i.e.* one for which $\mu < \nu \,.\supset.\, x_\mu < x_\nu$.

In general, the propositions of the present section are only important when P and Q are series. If our assertions are not to be trivial, we must have $\exists ! C\text{‘}Q \cap \text{G‘}R$ and $\exists ! C\text{‘}P \cap R\text{“}C\text{‘}Q$, *i.e.* there must be arguments in $C\text{‘}Q$ which lead to values in $C\text{‘}P$. It will also generally happen that the function is one-valued, *i.e.* that $R \epsilon 1 \rightarrow \text{Cls}$. But the above conditions, though necessary to the *importance* of our propositions, are in general much narrower than the hypotheses that are necessary for the *truth* of our propositions.

The present section is wholly self-contained, that is to say, its propositions are not referred to in the sequel. We have, in this section, carried the subject as far as seemed suitable for the present work; its further development belongs to treatises on analysis.

We begin (*230) with a general conception which is involved in the notion of convergency. We shall say that the values of a function converge (or, simply, that the function itself converges) into the class α, if for late enough arguments the values always belong to the class α, *i.e.* if there is a term y such that, if yQ_*z, $R\text{‘}z \epsilon \alpha$, or, to avoid assuming that R is one-valued, $\overrightarrow{R}\text{‘}z \subset \alpha$. Thus the values of the function converge into the class α if

$$(\exists y) . y \epsilon C\text{‘}Q \cap \text{G‘}R . R\text{“}\overleftarrow{Q_*}\text{‘}y \subset \alpha.$$

If a term y is one such that, from y onward, all values belong to α, we write $y \epsilon R\overline{Q}_{\text{cn}}\,\alpha$ (where "cn" stands for "convergent"), *i.e.* we put

$$R\overline{Q}_{\text{cn}}\,\alpha = \hat{y}\,\{y \epsilon C\text{‘}Q \cap \text{G‘}R . R\text{“}\overleftarrow{Q_*}\text{‘}y \subset \alpha\} \quad \text{Df.}$$

When there is such a y, *i.e.* when the function converges into the class α, we write "$RQ_{\text{cn}}\,\alpha$," *i.e.* we put

$$Q_{\text{cn}} = \hat{R}\hat{\alpha}\,(\exists ! R\overline{Q}_{\text{cn}}\,\alpha) \quad \text{Df.}$$

"$RQ_{\text{cn}}\,\alpha$" may be read "R is Q-convergent into α." This means that for arguments sufficiently late in the Q-series, the value of the function is always a member of α. Thus *e.g.* if $R\text{‘}x = 1/x$, and $\alpha = \hat{y}\,(y < 1)$, $RQ_{\text{cn}}\,\alpha$, and if $z > 1$, $z \epsilon R\overline{Q}_{\text{cn}}\,\alpha$.

We next consider (*231) *limiting sections* and *ultimate oscillations* of functions. For this purpose, we proceed as follows. If $RQ_{\text{cn}}\,\alpha$, then $P_*\text{“}\alpha$ is a section of the P-series such that, for sufficiently late arguments, the values of the function must belong to $P_*\text{“}\alpha$. Hence if we take all possible values of α for which $RQ_{\text{cn}}\alpha$, and take the logical product of all the resulting sections $P_*\text{“}\alpha$, we get a section containing all the "ultimate" values of the function; moreover this is obviously the smallest section which has this property, because, if we take any section β which contains all the "ultimate" values, we have $RQ_{\text{cn}}\,\beta$, and $P_*\text{“}\beta = \beta$, and therefore the logical product in question is contained in β. The logical product in question is

$$p\text{‘}P_*\text{“‘}\overleftarrow{Q_{\text{cn}}}\text{‘}R.$$

In order to avoid trivial exceptions which arise when $C\text{‘}Q \cap \text{Ɑ}\text{‘}R = \Lambda$, we define the "limiting section" as

$$p\text{‘}P_{*}\text{“‘}\overleftarrow{Q}_{\mathrm{cn}}\text{‘}R \cap C\text{‘}P.$$

This "limiting section" we denote by $P\overline{R}_{\mathrm{sc}}Q$, where the letters "sc" stand for "section." Thus we put

$$P\overline{R}_{\mathrm{sc}}Q = p\text{‘}P_{*}\text{“‘}\overleftarrow{Q}_{\mathrm{cn}}\text{‘}R \cap C\text{‘}P \quad \text{Df.}$$

$P\overline{R}_{\mathrm{sc}}Q$ is the class of those members x of the series P which are such that, given any argument however late, there are still arguments as late or later for which the value of the function is not less than x. In like manner, $\breve{P}\overline{R}_{\mathrm{sc}}Q$, which we will call the "limiting upper section," consists of those members x of the series P which are such that, given any argument however late, there are still arguments as late or later for which the value of the function is not greater than x. Thus the product of $P\overline{R}_{\mathrm{sc}}Q$ and $\breve{P}\overline{R}_{\mathrm{sc}}Q$ is the smallest stretch which contains all the "ultimate" values of the function, *i.e.* it is the stretch consisting of those terms x which are such that, however late an argument we take, there are arguments as late or later for which the value of the function is not greater than x, and also arguments for which it is not less than x. Thus the product of $P\overline{R}_{\mathrm{sc}}Q$ and $\breve{P}\overline{R}_{\mathrm{sc}}Q$ represents what we may call the "ultimate oscillation" of the function. We shall denote it by $P\overline{R}_{\mathrm{os}}Q$, putting

$$P\overline{R}_{\mathrm{os}}Q = P\overline{R}_{\mathrm{sc}}Q \cap \breve{P}\overline{R}_{\mathrm{sc}}Q \quad \text{Df.}$$

We may express $P\overline{R}_{\mathrm{sc}}Q$ in a form not involving Q_{cn}, namely (*231·12)

$$P\overline{R}_{\mathrm{sc}}Q = p\text{‘}P_{*}\text{“‘}R\text{“‘}\overleftarrow{Q_{*}}\text{“}(C\text{‘}Q \cap \text{Ɑ}\text{‘}R) \cap C\text{‘}P.$$

This formula for $P\overline{R}_{\mathrm{sc}}Q$ may be elucidated by the following considerations. If y is any member of $C\text{‘}Q$, then $\text{Ɑ}\text{‘}R \cap \overleftarrow{Q_{*}}\text{‘}y$ consists of all arguments from y onwards. Hence $R\text{“}(\text{Ɑ}\text{‘}R \cap \overleftarrow{Q_{*}}\text{‘}y)$, *i.e.* $R\text{“}\overleftarrow{Q_{*}}\text{‘}y$, consists of all values of the function for arguments from y onwards. Hence $P_{*}\text{“}R\text{“}\overleftarrow{Q_{*}}\text{‘}y$ consists of all members of the P-series which are equalled or surpassed by values of the function for arguments equal to or later than y. Now if a term x belongs to the class $P_{*}\text{“}R\text{“}\overleftarrow{Q_{*}}\text{‘}y$ for every argument y, it is a term such that, however far up the argument-series Q we go, we shall still find values as great as or greater than x. When this is the case, we may say that x is P-persistent. In this case, x may be regarded as not greater than the "ultimate" values of the function. Now the class of arguments concerned is $C\text{‘}Q \cap \text{Ɑ}\text{‘}R$. Hence the class of P-persistent terms is

$$p\text{‘}P_{*}\text{“‘}R\text{“‘}\overleftarrow{Q_{*}}\text{“}(C\text{‘}Q \cap \text{Ɑ}\text{‘}R),$$

where the factor $C\text{‘}P$ may be added in order to accommodate the formula to the trivial case where $C\text{‘}Q \cap \text{Ɑ}\text{‘}R = \Lambda$ (the only case in which the factor $C\text{‘}P$

makes any difference). Thus the class of P-persistent terms is the limiting section. Similarly the $\breve{P}$-persistent terms are the limiting upper section. These are the terms which are not less than the "ultimate" values of the function. Thus the product $P\overline{R}_{os}Q$ is the terms which are neither greater than all ultimate values, nor less; hence it is the class of ultimate values, which may be appropriately called the "ultimate oscillation."

It will be seen that $P\overline{R}_{os}Q$, being the product of an upper and lower section, is itself a stretch: we may call it (alternatively) the "limiting stretch." It consists of all members x of the P-series such that the function does not, however great we make the argument, become and remain less than x, nor yet become and remain greater than x. If $P\overline{R}_{os}Q$ consists of a single term, that term is the limit of the function as the argument travels up the series Q. (This is, of course, in general different from the limit of the values of the function considered simply as a class of members of $C'P$, *i.e.* it is different from $\mathrm{lt}_P{}'R``C'Q$.) If $P\overline{R}_{os}Q$ does not consist of a single term or none, we shall have two limits to consider, namely $\mathrm{limax}_P{}'P\overline{R}_{os}Q$ and $\mathrm{limin}_P{}'P\overline{R}_{os}Q$, which give the two boundaries of the ultimate values of the function. When the class $P\overline{R}_{os}Q$ is null, the function may be regarded as having a definite limit: in this case, $P\overline{R}_{sc}Q$ and $\breve{P}\overline{R}_{sc}Q$ are the two parts of an "irrational" Dedekind cut, *i.e.* a cut in which the first portion has no maximum and the second no minimum. Thus $P\overline{R}_{os}Q \in 0 \cup 1$ is the condition for a definite limit of the function as the argument grows indefinitely.

The above gives the generalization of the limit of a function when the argument may be any member of $C'Q \cap \text{Cl}'R$. In order to obtain limits for other classes of arguments, it is only necessary, as a rule, to limit the field of Q to the class of arguments in question, *i.e.* to replace Q by $Q \upharpoonright \alpha$ (cf. *232). In order, however, to avoid vexatious and trivial exceptions arising when $\alpha \in 1$, it is more convenient to replace Q by $Q_* \upharpoonright \alpha$. Thus the section of P defined by the class of arguments α is $P\overline{R}_{sc}(Q_* \upharpoonright \alpha)$. We put

$$(P\overline{R}Q)_{sc}{}'\alpha = P\overline{R}_{sc}(Q_* \upharpoonright \alpha) \quad \text{Df.}$$

This definition is useful because we very often wish to be able to exhibit the limiting section defined by α as a function of α. The section $(P\overline{R}Q)_{sc}{}'\alpha$ is such that, if x is any member of it, and y is any argument belonging to α, there is in α an argument equal to or later than y, for which the function has a value equal to or later than x. Thus x is such that the function does not ultimately become less than x as the argument increases in the class α. The limit or maximum of such terms as x is the limit or maximum of the ultimate values of the function as the argument approaches the top of α. The class of ultimate values is

$$(P\overline{R}Q)_{sc}{}'\alpha \cap (\breve{P}\overline{R}Q)_{sc}{}'\alpha, \text{ which we call } (P\overline{R}Q)_{os}{}'\alpha.$$

If the function has a definite limit as the argument increases in α, the class of ultimate values must not contain more than one term.

Our next number (*233) deals with the limit of a function for a given argument. The limit or maximum of the class of ultimate values is not necessarily the value for the limit of α. It will be found, however, that, with a suitable hypothesis, the limiting section $(P\bar{R}Q)_{sc}`\alpha$ depends only upon $Q_*``(\alpha \cap \text{Cl}`R)$, and if $\alpha \cap \text{Cl}`R$ has no maximum, it depends only upon $Q``(\alpha \cap \text{Cl}`R)$. Thus if $\alpha \cap \text{Cl}`R$ and $\beta \cap \text{Cl}`R$ both have the same limit, they define the same limiting section. Hence if $a$ is the limit of $\alpha$, the limiting section of $\alpha$ is $(P\bar{R}Q)_{sc}`\overrightarrow{Q}`a$. The upper limit of this is the upper limit of the ultimate values as the argument approaches a from below. We put

$$R\,(PQ)`a = \text{limax}_P`(P\bar{R}Q)_{sc}`\overrightarrow{Q}`a \quad \text{Df.}$$

We have thus four limits of the function as the argument approaches a, namely

$$R\,(PQ)`a,\ \ R\,(\breve{P}Q)`a,\ \ R\,(P\breve{Q})`a,\ \ R\,(\breve{P}\breve{Q})`a.$$

If R is a continuous function, these four are all equal to $R`a$; but in general they are different from each other and from $R`a$. The subject of the continuity of functions is dealt with in *234. When $R\,(PQ)`a = R\,(\breve{P}Q)`a$, each is the limit of the function for the argument a for approaches from below. It should be observed that if R is defined for a set of arguments which are dense in Q, *i.e.* if $\delta_Q`\text{Cl}`R = C`Q$, then $R\,(PQ)`a$ and $R\,(\breve{P}Q)`a$ are defined for all arguments in $C`Q$.

$*230$. ON CONVERGENTS

Summary of $*230$.

In the present number, we have to consider the notion of a function converging into a given class, or, as we may express it, the notion that the value of the function "ultimately" belongs to the given class. If R is the function in question, α the given class, and Q a series to which the arguments belong, we say that "R is Q-convergent into α" if there is an argument y such that, for all arguments from y onward (in the Q-order), the value of the function is an α. That is, R is Q-convergent into α if

$$(\exists y) \,.\, y \in C\text{‘}Q \cap \text{ᗡ}\text{‘}R \,.\, R\text{“}\overleftarrow{Q_*}\text{‘}y \subset \alpha.$$

A term y which is of this nature is said to belong to the class $R\overline{Q}_{\mathrm{cn}}\alpha$. Thus R is Q-convergent into α if the class $R\overline{Q}_{\mathrm{cn}}\alpha$ is not null. Hence we have the following pair of definitions:

$$R\overline{Q}_{\mathrm{cn}}\alpha = C\text{‘}Q \cap \text{ᗡ}\text{‘}R \cap \hat{y}\,(R\text{“}\overleftarrow{Q_*}\text{‘}y \subset \alpha) \quad \mathrm{Df},$$

$$Q_{\mathrm{cn}} = \hat{R}\hat{\alpha}\,(\exists \,!\, R\overline{Q}_{\mathrm{cn}}\alpha) \qquad \mathrm{Df}.$$

In all the cases that have any importance, R will be a one-valued function (*i.e.* a one-many relation), Q will be a series, and $C\text{‘}Q \cap \text{ᗡ}\text{‘}R$ will be a class having no maximum in Q. For, if $C\text{‘}Q \cap \text{ᗡ}\text{‘}R$ has a maximum in Q, then the classes into which R converges are simply those to which the value for this maximum belongs. The following propositions, though only *important* under the above circumstances, are in general *true* under much wider hypotheses.

It is possible to generalize still further the notion of convergence, so as to apply to any property which belongs to R when confined to sufficiently late arguments. For this purpose, we have to consider $R \upharpoonright \overleftarrow{Q_*}\text{‘}z$, where z is to be confined to terms later than or equal to some term y. If, under these circumstances, $R \upharpoonright \overleftarrow{Q_*}\text{‘}z$ always belongs to the class λ, we may say that R ultimately becomes a λ. We may put

$$R\overline{Q}_{\mathrm{cng}}\lambda = \hat{y}\,\{y \in C\text{‘}Q \cap \text{ᗡ}\text{‘}R : yQ_*z \,.\, \supset_z .\, R \upharpoonright \overleftarrow{Q_*}\text{‘}z \in \lambda\} \quad \mathrm{Df},$$

$$Q_{\mathrm{cng}} = \hat{R}\hat{\lambda}\,(\exists \,!\, R\overline{Q}_{\mathrm{cng}}\lambda) \qquad \mathrm{Df}.$$

This is the general conception of which Q_{cn} is a particular case; in fact,

$$\vdash : RQ_{\mathrm{cn}}\alpha \,.\equiv .\, RQ_{\mathrm{cng}}(\breve{\mathrm{D}}\text{“}\mathrm{Cl}\text{‘}\alpha).$$

Q_{cng} will have to be used when the ultimate properties of the function with which we are concerned are not properties of its values; but when they are properties of its values, Q_{cn} enables us to deal with them more easily than Q_{cng}

In this number, we prove the following propositions among others:

$*230{\cdot}171$. $\vdash : y \in R\overline{Q}_{\mathrm{cn}}(\overleftarrow{P_*}\text{‘}x) \,.\supset .\, x \in P_*\text{“}R\text{“}\overleftarrow{Q_*}\text{‘}y$

$*230\cdot211.\ \vdash :. \alpha \subset \beta . \supset : RQ_{cn}\alpha . \supset . RQ_{cn}\beta$

$*230\cdot253.\ \vdash :. R``C`Q \subset \alpha . \supset : RQ_{cn}\alpha . \equiv . \exists ! C`Q \cap \text{Ꮖ}`R .$
$\equiv . \exists ! R``C`Q . \equiv . \dot{\exists} ! (R \upharpoonright C`Q)$

$*230\cdot4.\ \ \vdash . R\bar{Q}_{cn}\alpha = \text{Ꮖ}`R \cap \breve{Q}_*``(R\bar{Q}_{cn}\alpha)$

$*230\cdot42.\ \ \vdash :. Q_* \epsilon \text{ connex} . \supset : RQ_{cn}\alpha . RQ_{cn}\beta . \equiv . RQ_{cn}(\alpha \cap \beta)$

$*230\cdot53.\ \ \vdash :. Q \epsilon \text{ trans} \cap \text{connex} . E ! \max_Q`\text{Ꮖ}`R . \supset : RQ_{cn}\alpha . \equiv . \overrightarrow{R}`\max_Q`\text{Ꮖ}`R \subset \alpha$

In virtue of this proposition, the case when $E ! \max_Q`\text{Ꮖ}`R$ is uninteresting, and in order to obtain interesting interpretations of our propositions, it is necessary to suppose that $\text{Ꮖ}`R$ has no maximum. Similarly when, in later numbers, we consider $\text{Ꮖ}`R \cap \overrightarrow{Q}`x$, we shall only obtain interesting results when this has no maximum, which requires that $Q$ should be a compact series ($Q^2 = Q$) and $\text{Ꮖ}`R$ should be dense in Q. These assumptions are, however, not usually required for the *truth* of our propositions.

$*$231. LIMITING SECTIONS AND ULTIMATE OSCILLATION OF A FUNCTION

Summary of $*$231.

In the present number we are concerned with the limiting section defined in a series P, to which the values of a function R belong, as the arguments to the function increase in the argument-series Q. That is, we are concerned with the section consisting of those terms x of $C\text{‘}P$ which are such that, however great the argument to R becomes, there are still values at least as great as x. Such terms as x may be said to be P-persistent; x is P-persistent if the function does not ultimately become and remain less than x. The class of persistent terms is called the *limiting section.* The limiting section may be defined as follows. If α is any class into which R is Q-convergent, then the section $P_*\text{“}\alpha$ is such that the values of the function are ultimately contained in it. The product of such terms as $P_*\text{“}\alpha$ is the smallest section having this property. Hence if x be any member of this section, then ultimately (*i.e.* for arguments far enough along the Q series) the values of the function R do not persistently remain less than x in the P series. Thus the product of such terms as $P_*\text{“}\alpha$ is the limiting section, and we may therefore put

$$P\overline{R}_{sc}Q = p\text{‘}P_*\text{“‘}\overleftarrow{Q}_{cn}\text{‘}R \cap C\text{‘}P \quad \text{Df},$$

where the letters "sc" are intended to suggest "section." (The factor $C\text{‘}P$ on the right is superfluous except when $\overleftarrow{Q}_{cn}\text{‘}R = \Lambda$, *i.e.* when $C\text{‘}Q \cap \text{ᗡ}\text{‘}R = \Lambda$.)

We will call the limiting section of $\breve{P}$, *i.e.* $\breve{P}\overline{R}_{sc}Q$, the "limiting upper section." It will be seen that if x is a member of $\breve{P}\overline{R}_{sc}Q$, then the function does not ultimately become and remain, as far as some of its arguments are concerned, greater than x, that is, however great we make the argument, we still find values not greater than x. Hence if x belongs to both $P\overline{R}_{sc}Q$ and $\breve{P}\overline{R}_{sc}Q$, we find values not less than x and values not greater than x however great we make the argument. This class, $P\overline{R}_{sc}Q \cap \breve{P}\overline{R}_{sc}Q$, may therefore be regarded as the class of ultimate values of the function. We will call it the "ultimate oscillation" of the function, since, as the argument approaches ∞, the value of the function ultimately oscillates in this stretch of P, and no smaller stretch has the same property. We will denote this class by "$P\overline{R}_{os}Q$," where "os" is intended to suggest "oscillation." $P\overline{R}_{os}Q$ is a stretch in $C\text{‘}P$, because it is the product of two sections. Hence we shall also call it the "limiting stretch." When the function has a definite limit as the argument approaches ∞, the limiting stretch must not contain more than one term.

Limits of functions for arguments x in the middle of $C\text{‘}Q \cap \text{ᗡ}\text{‘}R$, which will be considered later, are derived from the limits considered in the present number by limiting the field of Q to predecessors of x.

In this number we prove the following propositions among others:

$*231{\cdot}103.\ \vdash . P\overline{R}_{os}Q = P_{po}\overline{R}_{os}Q = P_*\overline{R}_{os}Q$

$*231{\cdot}12.\ \vdash . P\overline{R}_{sc}Q = p‘P_*‘‘‘R‘‘‘\overleftarrow{Q_*}‘‘(C‘Q \cap \text{Ꭺ}‘R) \cap C‘P$

$*231{\cdot}13.\ \vdash . P\overline{R}_{sc}Q \in \text{sect}‘P$

$*231{\cdot}141.\ \vdash : Q_* \in \text{connex} . RQ_{cn}(\overleftarrow{P_*}‘x) . \supset . x \in P\overline{R}_{sc}Q$

$*231{\cdot}191.\ \vdash : P_{po} \in \text{connex} . \exists ! P\overline{R}_{os}Q . \supset .$

$$P\overline{R}_{sc}Q = P_*‘‘(P\overline{R}_{os}Q) . P‘‘(P\overline{R}_{sc}Q) = P_{po}‘‘(P\overline{R}_{os}Q)$$

$*231{\cdot}192.\ \vdash :. P_{po} \in \text{connex} . \exists ! P\overline{R}_{os}Q . \exists ! P\overline{R}_{os}Q' . \supset :$

$$P\overline{R}_{os}Q = P\overline{R}_{os}Q' . \equiv . P\overline{R}_{sc}Q = P\overline{R}_{sc}Q' . \breve{P}\overline{R}_{sc}Q = \breve{P}\overline{R}_{sc}Q'$$

$*231{\cdot}193.\ \vdash : P_{po} \in \text{Ser} . P\overline{R}_{os}Q \in 1 . \supset .$

$$P\overline{R}_{os}Q = \iota‘\max_P‘(P\overline{R}_{sc}Q) = \iota‘\min_P‘(\breve{P}\overline{R}_{sc}Q)$$

This proposition is frequently used in the present section.

In all ordinary circumstances, we shall have $C‘P = P\overline{R}_{sc}Q \cup \breve{P}\overline{R}_{sc}Q$, so that if the upper and lower limiting sections do not have more than one term in common (*i.e.* if $P\overline{R}_{os}Q \in 1$), they define a Dedekind cut in P. The following propositions are concerned with this fact:

$*231{\cdot}202.\ \vdash : P_*, Q_* \in \text{connex} . \exists ! P\overline{R}_{sc}Q . \supset . C‘P - (P\overline{R}_{sc}Q) \subset \breve{P}\overline{R}_{sc}Q$

$*231{\cdot}21.\ \vdash : P_*, Q_* \in \text{connex} . C‘Q \cap \text{Ꭺ}‘R \subset Q_*‘‘\breve{R}‘‘C‘P . \supset .$

$$C‘P = P\overline{R}_{sc}Q \cup \breve{P}\overline{R}_{sc}Q$$

$*231{\cdot}22.\ \vdash : P_*, Q_* \in \text{connex} . R‘‘C‘Q \subset C‘P . \supset . C‘P = P\overline{R}_{sc}Q \cup \breve{P}\overline{R}_{sc}Q$

Note that "$R‘‘C‘Q \subset C‘P$" is the hypothesis that for arguments belonging to $C‘Q$, the values belong to $C‘P$.

$*231{\cdot}24.\ \vdash : P_* \in \text{connex} . R‘‘C‘Q \subset C‘P . \sim\{RQ_{cn}(\overrightarrow{P_*}‘x)\} . \supset . \overrightarrow{P_*}‘x \subset P\overline{R}_{sc}Q$

$*231{\cdot}01.\quad P\overline{R}_{sc}Q = p‘P_*‘‘‘\overleftarrow{Q}_{cn}‘R \cap C‘P \quad$ Df

$*231{\cdot}02.\quad P\overline{R}_{os}Q = P\overline{R}_{sc}Q \cap \breve{P}\overline{R}_{sc}Q \quad$ Df

$*231{\cdot}1.\quad \vdash . P\overline{R}_{sc}Q = p‘P_*‘‘‘\overleftarrow{Q}_{cn}‘R \cap C‘P \quad [(*231{\cdot}01)]$

$*232$. ON THE OSCILLATION OF A FUNCTION AS THE ARGUMENT APPROACHES A GIVEN LIMIT

Summary of $*232$.

In the preceding number, we considered the ultimate oscillation of a function when the argument grows without limit. If, in the propositions of the last number, we confine the field of Q to $\overrightarrow{Q}\text{‘}x$, where $x \in \text{Ɑ}\text{‘}Q$, the ultimate oscillation becomes the ultimate oscillation as the argument approaches x from below. If the ultimate oscillation consists of a single term, this is the limit of the function as the argument approaches x from below. If, instead of confining the argument to $\overrightarrow{Q}\text{‘}x$, we confine it to any other class whose limit is x, we shall, under a very usual hypothesis, obtain the same value for the ultimate oscillation as if we confined it to $\overrightarrow{Q}\text{‘}x$. And more generally, under a similar hypothesis, if α and β are two classes of arguments which define the same section (*i.e.* such that $Q_*\text{“}\alpha = Q_*\text{“}\beta$), then, whether or not this section has a limit, the ultimate sections and the ultimate oscillation are the same for α as they are for β. Hence we are led to consider first the result of confining the field of Q, not to $\overrightarrow{Q}\text{‘}x$, but to any class α. In order not to have to exclude explicitly the case in which $\alpha \in 1$, we deal with $Q_* \upharpoonright \alpha$, not $Q \upharpoonright \alpha$. Hence we are led to the following definitions:

$*232{\cdot}01$. $(P\overline{R}Q)_{sc}\text{‘}\alpha = P\overline{R}_{sc}(Q_* \upharpoonright \alpha)$ Df

$*232{\cdot}02$. $(P\overline{R}Q)_{os}\text{‘}\alpha = P\overline{R}_{os}(Q_* \upharpoonright \alpha)$ Df

Most of the propositions of the present number are immediate consequences of corresponding propositions in $*231$. The most important application of the propositions of the present number is to the case where α is of the form $\overrightarrow{Q}\text{‘}x$, x being a member of $\delta_Q\text{‘}\text{Ɑ}\text{‘}R$. We may, in this case, take in place of $\overrightarrow{Q}\text{‘}x$ any other class of arguments (*e.g.* a progression of arguments $x_1, x_2, \ldots x_\nu, \ldots$) having x for its limit, without altering the limiting sections or the ultimate oscillation. Hence the limit of the function for a given argument (if it exists) may be determined by choosing any selection of arguments having the given argument as their limit (cf. $*233{\cdot}142$, below).

From the definition of $(P\overline{R}Q)_{sc}\text{‘}\alpha$ we obtain immediately

$*232{\cdot}11$. $\vdash :. \, x \in (P\overline{R}Q)_{sc}\text{‘}\alpha \,.\equiv :$

$$y \in \alpha \cap C\text{‘}Q \cap \text{Ɑ}\text{‘}R \,.\supset_y .\, x \in P_*\text{“}R\text{“}(\alpha \cap \overleftarrow{Q_*}\text{‘}y) : x \in C\text{‘}P$$

We prove that $(P\overline{R}Q)_{sc}\text{‘}\alpha = (P\overline{R}Q)_{sc}\text{‘}(\alpha \cap C\text{‘}Q \cap \text{Ɑ}\text{‘}R)$ ($*232{\cdot}131$), and that if $\alpha \cap C\text{‘}Q \cap \text{Ɑ}\text{‘}R = \Lambda$, the two limiting sections and the ultimate oscillation are all equal to $C\text{‘}P$ ($*232{\cdot}15$). Also we have

$*232{\cdot}14$. $\vdash : Q \in \text{trans} \cap \text{connex} \,.\, \alpha \cap C\text{‘}Q \sim\in 1 \,.\supset .\, (P\overline{R}Q)_{sc}\text{‘}\alpha = P\overline{R}_{sc}(Q \upharpoonright \alpha)$

Thus the substitution of Q_* for Q in our definitions has the effect of making them applicable to unit classes, and of enabling us to substitute the hypothesis $Q_* \epsilon \text{connex}$ for $Q \epsilon \text{trans} \cap \text{connex}$. But when Q is transitive and connected (and therefore when Q is a series), the substitution of Q_* for Q in the definitions makes no difference unless α is a unit class. This case is trivial, since the only interest of our definitions is when α has no maximum in Q.

From $*231{\cdot}22$ we obtain

$*232{\cdot}22$. $\vdash : P_*, Q_* \upharpoonright \alpha \epsilon \text{connex} \,.\, R``(\alpha \cap C`Q) \subset C`P \,.\, \supset .$
$$C`P = (P\bar{R}Q)_{sc}`\alpha \cup (\breve{P}\bar{R}Q)_{sc}`\alpha$$

We have next a set of propositions concerned in discovering circumstances under which two classes α and β which determine the same section in Q (and therefore have the same limit, if any) give the same values for the two limiting sections. For this purpose, it is only necessary to discover circumstances under which we may substitute $Q_*``(\alpha \cap \text{Ɑ}`R)$ for α. When this can be done, the ultimate oscillation of the function as the argument approaches the limit of α can be determined by taking any set of arguments having this limit. We have

$*232{\cdot}301$. $\vdash \,.\, (P\bar{R}Q)_{sc}`\alpha \subset (P\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{Ɑ}`R)$

$*232{\cdot}32$. $\vdash : (P\bar{R}Q)_{os}`Q_*``(\alpha \cap \text{Ɑ}`R) \epsilon 0 \cup 1 \,.\supset .\, (P\bar{R}Q)_{os}`\alpha \epsilon 0 \cup 1$

Thus if the function has a limit as the argument approaches the limit of $Q_*``(\alpha \cap \text{Ɑ}`R)$, it also has a limit as the argument approaches the limit of α.

$*232{\cdot}33$. $\vdash : P_*, Q_* \upharpoonright \alpha \epsilon \text{connex} \,.\, R``(\alpha \cap C`Q) \subset C`P \,.\, \supset .$
$$(P\bar{R}Q)_{sc}`\alpha \cup (\breve{P}\bar{R}Q)_{sc}`\alpha = (P\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{Ɑ}`R) \cup (\breve{P}\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{Ɑ}`R) = C`P$$
whence

$*232{\cdot}34$. $\vdash : \text{Hp}\, *232{\cdot}33 \,.\, (P\bar{R}Q)_{os}`Q_*``(\alpha \cap \text{Ɑ}`R) = \Lambda \,.\supset .$
$$(P\bar{R}Q)_{sc}`\alpha = (P\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{Ɑ}`R) \,.\, (\breve{P}\bar{R}Q)_{sc}`\alpha = (\breve{P}\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{Ɑ}`R)$$

We have also

$*232{\cdot}341$. $\vdash : P_* \epsilon \text{connex} \,.\, \exists ! (P\bar{R}Q)_{os}`\alpha \,.\, (P\bar{R}Q)_{os}`Q_*``(\alpha \cap \text{Ɑ}`R) \epsilon 1 \,.\supset .$
$$(P\bar{R}Q)_{sc}`\alpha = (P\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{Ɑ}`R) \,.\, (\breve{P}\bar{R}Q)_{sc}`\alpha = (\breve{P}\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{Ɑ}`R)$$

Hence we arrive at the conclusion that, if P_{po} is a series, and x is the limit of the function for the class $Q_*``(\alpha \cap \text{Ɑ}`R)$, if $x$ is a member of $(P\bar{R}Q)_{sc}`\alpha$, it is its maximum ($*232{\cdot}352$), while if x is not a member of $(P\bar{R}Q)_{sc}`\alpha$, it is its sequent ($*232{\cdot}356$), assuming $(P\bar{R}Q)_{sc}`\alpha \cup (\breve{P}\bar{R}Q)_{sc}`\alpha = C`P$, which, as we saw ($*233{\cdot}22$), is generally the case, and assuming also $P \epsilon \text{Ser}$. On the other hand, if $(P\bar{R}Q)_{sc}`\alpha$ has no maximum, $x$ is the minimum of $(\breve{P}\bar{R}Q)_{sc}`\alpha$; and if $(P\bar{R}Q)_{sc}`\alpha$ has a maximum other than $x$, this is $P_1`x$

(*232·357·358). This latter case is impossible unless x has an immediate predecessor. Hence we arrive at the following proposition:

***232·38.** $\vdash : P \epsilon \text{Ser} . Q_* \upharpoonright \alpha \epsilon \text{connex} . R``(\alpha \cap C`Q) \subset C`P .$
$(P\bar{R}Q)_{os}`Q_*``(\alpha \cap \text{G}`R) \epsilon 0 \cup (1 - \text{Cl}`C`P_1) . \supset .$
$\overrightarrow{\text{limax}}_P`(P\bar{R}Q)_{sc}`\alpha = \overrightarrow{\text{limax}}_P`(P\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{G}`R) .$
$\overrightarrow{\text{limin}}_P`(\breve{P}\bar{R}Q)_{sc}`\alpha = \overrightarrow{\text{limin}}_P`(\breve{P}\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{G}`R)$

Applying this to a series having Dedekindian continuity, we know that $P_1 = \Lambda$, and that the limax and limin always exist. Hence

***232·39.** $\vdash :. P \epsilon \text{Ser} \cap \text{Ded} . P^2 = P . Q_* \epsilon \text{connex} . R``C`Q \subset C`P . \supset :$
$(P\bar{R}Q)_{os}`Q_*``(\alpha \cap \text{G}`R) \epsilon 0 \cup 1 . \supset_\alpha .$
$\text{limax}_P`(P\bar{R}Q)_{sc}`\alpha = \text{limax}_P`(P\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{G}`R) =$
$\text{limin}_P`(\breve{P}\bar{R}Q)_{sc}`\alpha = \text{limin}_P`(\breve{P}\bar{R}Q)_{sc}`Q_*``(\alpha \cap \text{G}`R)$

That is to say, if the value-series P has Dedekindian continuity, and contains all values for arguments in $C`Q$, then, provided the function has a definite limit for the class $Q_*``(\alpha \cap \text{G}`R)$, this is its limit also for the class α; that is to say, any collection of arguments having the same limit or maximum as a given section will give the same limit for the function.

***232·01.** $(P\bar{R}Q)_{sc}`\alpha = P\bar{R}_{sc}(Q_* \upharpoonright \alpha)$ Df

***232·02.** $(P\bar{R}Q)_{os}`\alpha = P\bar{R}_{os}(Q_* \upharpoonright \alpha)$ Df

***232·1.** $\vdash . (P\bar{R}Q)_{sc}`\alpha = P\bar{R}_{sc}(Q_* \upharpoonright \alpha)$ [(*232·01)]

$*$233. ON THE LIMITS OF FUNCTIONS

Summary of $*$233.

There are four limits of a function as the argument approaches some term a in the argument-series, namely the upper and lower limits of the ultimate oscillation for approaches from below and above respectively. If the ultimate oscillation for approaches to a from below reduces to a single term, *i.e.* if $(P\bar{R}Q)_{os}\text{‘}\overrightarrow{Q}\text{‘}a \in 1$, that one term is *the* limit of the function for approaches to a from below. If this one term is also the ultimate oscillation for approaches from above, we may call it simply *the* limit of the function for the argument a. This may or may not (when it exists) be equal to the value for the argument a. It is characteristic of *continuous* functions that *the* limit exists for every argument, and is always equal to the value for that argument. Continuous functions will be considered in $*$234.

The upper limit or maximum of the ultimate oscillation as the argument approaches a is the upper limit or maximum of the ultimate section. Hence if we put

$$R(PQ)\text{‘}a = \text{limax}_P\text{‘}(P\bar{R}Q)_{sc}\text{‘}\overrightarrow{Q}\text{‘}a \quad \text{Df},$$

the four limits of the function as the argument approaches a will be

$$R(PQ)\text{‘}a, \quad R(\breve{P}Q)\text{‘}a, \quad R(P\breve{Q})\text{‘}a, \quad R(\breve{P}\breve{Q})\text{‘}a.$$

It will be seen that $R(PQ)\text{‘}a$ is a function of $\overrightarrow{Q}\text{‘}a$. It may happen that, if we put α in place of $\overrightarrow{Q}\text{‘}a$, the function will have a definite limit as the argument increases in α, although α has no limit or maximum. Thus if, for example, Q consists of the series of rationals, and P of the series of real numbers, if α is a class of rationals not having a rational limit, we may regard the limit of the function (if it exists), as the argument increases in α, as the value of the function for the irrational limit of α. In this way we can extend the domain of definition of a function.

In order to be able to deal with the cases in which α has no limit, we put

$$(P\bar{R}Q)_{lmx}\text{‘}\alpha = \text{limax}_P\text{‘}(P\bar{R}Q)_{sc}\text{‘}\alpha \quad \text{Df.}$$

If P is a Dedekindian series, $(P\bar{R}Q)_{lmx}\text{‘}\alpha$ always exists. If we take α to be any segment of Q, we thus get a new function, derived from R, but having segments of Q instead of members of $C\text{‘}Q$ as its arguments. Thus if R had rationals for its arguments, this new function will have real numbers for its arguments. (Real numbers may be regarded as segments of the series of rationals.)

The function $R(PQ)`a$ is a particular case of the above; thus we take as our definition

$$R(PQ)`a = (P\bar{R}Q)_{lmx}`\overrightarrow{Q}`a \quad \text{Df},$$

or, what comes to the same thing,

$$R(PQ) = (P\bar{R}Q)_{lmx} \,|\, \overrightarrow{Q} \quad \text{Df}.$$

The following propositions of this number are important:

$*233{\cdot}15.\ \vdash :. P \in \text{Ser} \cap \text{Ded} . (P\bar{R}Q)_{sc}`\alpha \cup (\breve{P}\bar{R}Q)_{sc}`\alpha = C`P . (P\bar{R}Q)_{os}`\alpha = \Lambda . \supset :$
$(P\bar{R}Q)_{lmx}`\alpha = (\breve{P}\bar{R}Q)_{lmx}`\alpha . \vee . \{(P\bar{R}Q)_{lmx}`\alpha\} P_1 \{(\breve{P}\bar{R}Q)_{lmx}`\alpha\}$

$*233{\cdot}16.\ \vdash :. P \in \text{Ser} \cap \text{Ded} . P^2 = P . Q_* \in \text{connex} . R``C`Q \subset C`P . \supset :$
$(P\bar{R}Q)_{os}`\alpha \in 0 \cup 1 . \supset_\alpha . (P\bar{R}Q)_{lmx}`\alpha = (\breve{P}\bar{R}Q)_{lmx}`\alpha$

$*233{\cdot}2$—$\cdot25$ are applications of the more important of the propositions $*232{\cdot}34$—$\cdot39$, showing circumstances under which the limit of the function for the class α is the same as for the class $Q_*``(\alpha \cap \text{Ɑ}`R)$.

$*233{\cdot}4$ and following propositions apply the earlier propositions of $*233$ to the case where α is replaced by $\overrightarrow{Q}`a$, and therefore $(P\bar{R}Q)_{lmx}`\alpha$ is replaced by $R(PQ)`a$. We have

$*233{\cdot}43.\ \vdash : P_{po} \in \text{Ser} . (P\bar{R}Q)_{os}`\overrightarrow{Q}`a \in 1 . \supset .$
$R(PQ)`a = R(\breve{P}Q)`a = \breve{\iota}`(P\bar{R}Q)_{os}`\overrightarrow{Q}`a$

$*233{\cdot}433.\ \vdash :. P \in \text{Ser} . Q_* \upharpoonright \overrightarrow{Q}`a \in \text{connex} . R``\overrightarrow{Q}`a \subset C`P . (P\bar{R}Q)_{os}`\overrightarrow{Q}`a = \Lambda .$
$\text{E} ! \, R(PQ)`a . \text{E} ! \, R(\breve{P}Q)`a . \supset :$
$R(PQ)`a = R(\breve{P}Q)`a . \vee . \{R(PQ)`a\} P_1 \{R(\breve{P}Q)`a\}$

$*233{\cdot}45.\ \vdash :. P \in \text{Ser} \cap \text{Ded} . P^2 = P . Q_* \in \text{connex} . R``C`Q \subset C`P . \supset :$
$R(PQ)`a = R(\breve{P}Q)`a . \equiv_a . (P\bar{R}Q)_{os}`\overrightarrow{Q}`a \in 0 \cup 1$

I.e. in a series having Dedekindian continuity, the necessary and sufficient condition that the two limits of the function as the argument approaches a from below should be equal is that the ultimate oscillation should not have more than one term.

We have next a set of propositions ($*233{\cdot}5$—$\cdot53$) on the possibility of replacing $\overrightarrow{Q}`a$ by a class α having a for its limit, without altering the limits of the function. We have to begin with

$*233{\cdot}5.\ \vdash : Q \in \text{Ser} . a = \text{lt}_Q`(\alpha \cap \text{Ɑ}`R) . \supset . \overrightarrow{Q}`a = Q_*``(\alpha \cap \text{Ɑ}`R)$

in virtue of $*207{\cdot}291$. Thence by earlier propositions of this number,

$*233{\cdot}512.\ \vdash :. \text{Hp}\,*233{\cdot}5 . P \in \text{Ser} . R``(\alpha \cap C`Q) \subset C`P . (P\bar{R}Q)_{os}`\overrightarrow{Q}`a = \iota`x . \supset :$
$x = R(PQ)`a = R(\breve{P}Q)`a : x = (P\bar{R}Q)_{lmx}`\alpha . \vee . (P\bar{R}Q)_{lmx}`\alpha P_1 x$

whence we obtain

$*233{\cdot}514.\ \vdash : \mathrm{Hp}\,*233{\cdot}512\,.\,x \sim\in C`P_1\,.\,\supset\,.\,x = (P\bar{R}Q)_{\mathrm{lmx}}`\alpha = (\breve{P}\bar{R}Q)_{\mathrm{lmx}}`\alpha$

Thus if P, Q are series, and x is the limit of the function for the argument a (x being a term which has no immediate successor or predecessor), x is the limit of the function for any class of arguments whose limit is a. Hence we arrive at the proposition

$*233{\cdot}53.\ \vdash : Q \in \mathrm{Ser}\,.\,P \in \mathrm{Ser} \cap \mathrm{Ded}\,.\,P^2 = P\,.\,R``C`Q \subset C`P\,.\,\alpha \subset \text{ฯ}`R\,.\,\mathrm{E}\,!\,\mathrm{lt}_Q`\alpha\,.$
$(P\bar{R}Q)_{\mathrm{os}}`Q_*``\alpha \in 0 \cup 1\,.\,\supset\,.$
$(P\bar{R}Q)_{\mathrm{lmx}}`\alpha = (\breve{P}\bar{R}Q)_{\mathrm{lmx}}`\alpha = R\,(PQ)`\mathrm{lt}_Q`\alpha = R\,(\breve{P}Q)`\mathrm{lt}_Q`\alpha$

Thus if P has Dedekindian continuity, and α is a class of arguments having a limit, and if the ultimate oscillation as the argument approaches this limit has not more than one term, the limit of the function for the class α exists, and is equal to the limit of the function for the argument $\mathrm{lt}_Q`\alpha$.

$*234$. CONTINUITY OF FUNCTIONS

Summary of $*234$.

In the present number we are concerned with the definition and analysis of the continuity of functions. The following definition of continuity is given by Dini*:

"We call it [the function] *continuous* for $x=a$, or in the point a, in which it has the value $f(a)$, if, for every positive number σ, different from 0 but as small as we please, there exists a positive number ϵ, different from 0, such that, for all values of δ which are numerically less than ϵ, the difference $f(a+\delta)-f(a)$ is numerically less than σ. In other words, $f(x)$ is continuous in the point $x=a$, where it has the value $f(a)$, if the limit of its values to the right and left of a is the same and equal to $f(a)$...."

By the second form of the above definition, the function R of previous numbers is to be called continuous at the point a if

$$R(PQ)\text{‘}a = R(\breve{P}Q)\text{‘}a = R(P\breve{Q})\text{‘}a = R(\breve{P}\breve{Q})\text{‘}a = R\text{‘}a.$$

The first form of the definition can also be so stated as to be free from any reference to number, and derivable from the ideas dealt with in the previous numbers of the present section. For this purpose, instead of "a positive number σ," we take an interval in which $R\text{‘}a$ is contained, say $P(z-w)$. Similarly the "values of δ which are numerically less than ϵ" are replaced by arguments in a certain interval containing a.

By $*233{\cdot}423$, if the limits of the function as the argument approaches a are to be all equal, a must not be the maximum or minimum of $\text{Ɑ}\text{‘}R$. We therefore take the interval containing a to be an interval in which the end-points are not included, say $Q(y-y')$. Thus our definition becomes

(A) $R\text{‘}a \in P(z-w) \,.\, \supset_{z,w} .$

$$(\exists y, y') \,.\, y, y' \in \text{Ɑ}\text{‘}R \,.\, a \in Q(y-y') \,.\, R\text{‘‘}Q(y \vdash\!\dashv y') \subset P(z-w)$$

We require further, what is tacitly assumed in Dini's definition, that $R\text{‘}a$ is a member of $C\text{‘}P$ which has no immediate predecessor or successor, *i.e.*

$$R\text{‘}a \in C\text{‘}P - C\text{‘}P_1.$$

In order to deal more easily with the above definition, we analyse it into the product of four factors, which concern respectively P and Q, $\breve{P}$ and Q, P and $\breve{Q}$, $\breve{P}$ and $\breve{Q}$. In the first place, it is obvious that (A) is the product of

(B) $R\text{‘}a \in P(z-w) \,.\, \supset_{z,w} \,.\, (\exists y) \,.\, y \in \text{Ɑ}\text{‘}R \,.\, y \in \overrightarrow{\breve{Q}}\text{‘}a \,.\, R\text{‘‘}Q(y \vdash a) \subset P(z-w)$

* *Theorie der Functionen einer veränderlichen reellen Grösse*, Chap. IV. § 30, p. 50.

and a factor obtained by substituting $\breve{Q}$ for Q in (B). If $Q_* \epsilon \text{connex}$, and $P_{po} \epsilon \text{Ser}$, (B) is the product of

(C) $R'a \,\epsilon\, \overrightarrow{P_{po}}'w \,.\, \supset_w \,.\, (\exists y) \,.\, y \,\epsilon\, \text{G}'R \,.\, y \,\epsilon\, \overrightarrow{Q}'a \,.\, R''Q\,(y \vdash a) \subset \overrightarrow{P_*}'w$

and a factor obtained by writing $\breve{P}$ for P and z for w in (C); and in virtue of $R'a \sim\epsilon\, C'P_1$, (C) becomes

$$R'a \,\epsilon\, \overrightarrow{P_{po}}'w \,.\, \supset_w \,.\, (\exists y) \,.\, y \,\epsilon\, \text{G}'R \,.\, y \,\epsilon\, \overrightarrow{Q}'a \,.\, R''Q\,(y \vdash a) \subset \overrightarrow{P_{po}}'w,$$

i.e. if Q is transitive,

(D) $R'a \,\epsilon\, \overrightarrow{P_{po}}'w \,.\, \supset_w \,.\, R\,(Q_* \upharpoonright \overrightarrow{Q}'a)_{cn}\,(\overrightarrow{P_{po}}'w)$

Hence the function is continuous for the argument a if a satisfies (D) and the three other hypotheses resulting from replacing P by $\breve{P}$, or Q by $\breve{Q}$, or P and Q by $\breve{P}$ and $\breve{Q}$. If we substitute x for $R'a$, and Q for $Q_* \upharpoonright \overrightarrow{Q}'a$, (D) becomes

(E) $\overrightarrow{P_{po}}''\overleftarrow{P_{po}}'x \subset \overleftarrow{Q_{cn}}'R$

Hence continuity can be studied by studying the hypothesis (E), and replacing x by $R'a$ and Q by $Q_* \upharpoonright \overrightarrow{Q}'a$.

The hypothesis (E) is an interesting one on its own account. We put

$$\text{sc}\,(P, Q)'R = C'P \cap \hat{x}\,(\overrightarrow{P_{po}}''\overleftarrow{P_{po}}'x \subset \overleftarrow{Q_{cn}}'R) \quad \text{Df.}$$

Thus "$x \,\epsilon\, \text{sc}\,(P, Q)'R$" means that x is a member of the value-series such that, if y is any later member, the function ultimately becomes less than y. If we put further

$$\text{os}\,(P, Q)'R = \text{sc}\,(P, Q)'R \cap \text{sc}\,(\breve{P}, Q)'R \quad \text{Df,}$$

then, if x is a member of $\text{os}\,(P, Q)'R$, the function ultimately becomes less than any later member of $C'P$, and greater than any earlier member. Hence x is the limit of the function as the argument increases indefinitely. Hence, if we substitute $Q_* \upharpoonright \overrightarrow{Q}'a$ for Q, and if $x \,\epsilon\, \text{os}\,(P, Q_* \upharpoonright \overrightarrow{Q}'a)'R$, x is the limit of the function as the argument approaches a from below, *i.e.*

$$R\,(PQ)'a = R\,(\breve{P}Q)'a = x.$$

(This is proved in $*234{\cdot}462$.) Hence, putting $R'a$ in place of x, the function is continuous from below at the point a if

$$R'a \,\epsilon\, \text{os}\,(P, Q_* \upharpoonright \overrightarrow{Q}'a)'R,$$

and is continuous from above if

$$R'a \,\epsilon\, \text{os}\,(P, \breve{Q}_* \upharpoonright \overleftarrow{Q}'a)'R.$$

These results, and various others connected with them, are proved below. The equivalence of Dini's two definitions is proved in $*234{\cdot}63$. It will be observed that practically nothing in the theory of continuous functions requires the use of numbers.

We use the symbol "$\text{ct}(PQ)`R$" for the class of arguments $a$ for which the limit of the function for approaches to $a$ from below is $R`a$. Thus, in virtue of what was said above, we may put

$$\text{ct}(PQ)`R = \hat{a}\{R`a \in \text{os}(P, Q_* \upharpoonright \overrightarrow{Q_{\text{po}}}`a)`R - C`P_1\} \quad \text{Df.}$$

Then a function is continuous at the point a if a belongs to the two classes $\text{ct}(PQ)`R$ and $\text{ct}(P\breve{Q})`R$. Hence we put

$$\text{contin}(PQ)`R = \text{ct}(PQ)`R \cap \text{ct}(P\breve{Q})`R \quad \text{Df.}$$

The function R is continuous with respect to P and Q if it is continuous for all arguments in $C`Q$. Thus we put

$$P\,\overline{\text{contin}}\,Q = \hat{R}\{\exists ! C`Q \cap \text{Ꭰ}`R \,.\, C`Q \cap \text{Ꭰ}`R \subset \text{contin}(PQ)`R\} \quad \text{Df.}$$

Our propositions in this number begin with the properties of $\text{sc}(P, Q)`R$ and $\text{os}(P, Q)`R$. We have

***234·103.** $\vdash : P_{\text{po}} \in \text{Ser} \,.\, \exists ! \text{os}(P, Q)`R \,.\, \supset . \, P\overline{R}_{\text{os}}Q \in 0 \cup 1$

Thus the hypothesis $\exists ! \text{os}(P, Q)`R$ enables us to use propositions of previous numbers having the hypothesis $P\overline{R}_{\text{os}}Q \in 0 \cup 1$.

The identification of our definitions with the usual definitions of continuity of functions proceeds by means of the proposition

***234·12.** $\vdash :: Q_* \in \text{connex} \,.\, \supset :. \, x \in \text{os}(P, Q)`R \cap \text{D}`P \cap \text{Ꭰ}`P \,.\, \equiv :$
$x \in \text{D}`P \cap \text{Ꭰ}`P : x \in P(z - w) \,.\, \supset_{z, w} . \, RQ_{\text{cn}}\{P(z - w)\}$

We have a collection of propositions dealing with the relations of $\text{sc}(P, Q)`R$ to $P\overline{R}_{\text{sc}}Q$ and $\breve{P}\overline{R}_{\text{sc}}Q$. $\text{sc}(P, Q)`R$ is an upper section of P (*234·131); $\text{sc}(P, Q)`R$ is the complement of $P``(P\overline{R}_{\text{sc}}Q)$, *i.e.* of $P\overline{R}_{\text{sc}}Q$ without its maximum (if any). This is expressed in the following proposition:

***234·174.** $\vdash : P_{\text{po}} \in \text{Ser} \,.\, Q_* \in \text{connex} \,.\, R``C`Q \subset C`P \,.\, \supset .$
$C`P \cap p`\overrightarrow{P_{\text{po}}}``\text{sc}(P, Q)`R = P``(P\overline{R}_{\text{sc}}Q) = C`P - \text{sc}(P, Q)`R$

We thus arrive at

***234·182.** $\vdash : P \in \text{Ser} \,.\, Q_* \in \text{connex} \,.\, R``C`Q \subset C`P \,.\, \supset .$
$\overrightarrow{\text{limax}}_P`(P\overline{R}_{\text{sc}}Q) = \overrightarrow{\text{min}}_P`\text{sc}(P, Q)`R$

Thus $\text{os}(P, Q)`R$ is contained in $\overrightarrow{\text{max}}_P`(P\overline{R}_{\text{sc}}Q) \cup \overrightarrow{\text{min}}_P`(\breve{P}\overline{R}_{\text{sc}}Q)$ (*234·201), and therefore has not more than two terms (*234·202). If $P\overline{R}_{\text{os}}Q$ has one term, this is the only member of $\text{os}(P, Q)`R$ (*234·203). If $\text{os}(P, Q)`R$ has two terms, they have the relation $P_1$ (*234·242); hence if $P$ is a compact series, and $\text{os}(P, Q)`R$ is not null, its only member is both $\text{limax}_P`(P\overline{R}_{\text{sc}}Q)$ and $\text{limin}_P`(\breve{P}\overline{R}_{\text{sc}}Q)$ (*234·25), while conversely, if $\text{limax}_P`(P\overline{R}_{\text{sc}}Q)$ and $\text{limin}_P`(\breve{P}\overline{R}_{\text{sc}}Q)$ are equal, each is the only member of $\text{os}(P, Q)`R$ (*234·251).

We now apply the above results to the limits of a function as its argument approaches the limit of a class α. This is done, as before, by substituting $Q_* \upharpoonright \alpha$ for Q. We arrive at the proposition (*234·33) that if P has Dedekindian continuity, and $\mathrm{os}(P, Q_* \upharpoonright \alpha)\text{‘}R$ is not null, its only member is both $(P\bar{R}Q)_{\mathrm{lmx}}\text{‘}\alpha$ and $(\breve{P}\bar{R}Q)_{\mathrm{lmx}}\text{‘}\alpha$, *i.e.* is the limit of the function as the argument increases in α.

We then take for α the particular value $\overrightarrow{Q_{\mathrm{po}}}\text{‘}a$, so that we become concerned with what happens when the argument approaches a from below. For the comparison of our definition of continuity with such definitions as the one quoted from Dini above, we have

***234·41.** $\vdash :: Q \in \mathrm{trans} \,.\, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a \in \mathrm{connex} \,.\supset :.$
$$x \in \mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R \cap \mathrm{D}\text{‘}P \cap \mathrm{Cl}\text{‘}P \,.\equiv:$$
$$x \in \mathrm{D}\text{‘}P \cap \mathrm{Cl}\text{‘}P : x \in P(z - w) \,.\supset_{z,w} .$$
$$(\exists y) \,.\, y \in \overrightarrow{Q}\text{‘}a \cap \mathrm{Cl}\text{‘}R \,.\, R\text{‘‘}Q(y \mapsto a) \subset P(z-w)$$

I.e. if x is neither the first nor the last member of the P-series, x belongs to $\mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R$ when, and only when, given any interval $P(z-w)$, however small, in which x is contained, there is an argument y earlier than a, such that the value of the function for all arguments earlier than a but not earlier than y lies in the interval $P(z-w)$.

We deduce from previous propositions that, with the usual hypothesis as to Q, if P is a Dedekindian series,
$$R(PQ)\text{‘}a = \mathrm{limin}_P\text{‘}\mathrm{sc}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R \quad (*234{\cdot}422),$$
and if P is a series and $\mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)$ is a unit class, its only member is both $R(PQ)\text{‘}a$ and $R(\breve{P}Q)\text{‘}a$, *i.e.* is the limit of the function for approaches to a from below (*234·43). The following proposition sums up our results:

***234·45.** $\vdash :. P \in \mathrm{Ser} \,.\, Q \in \mathrm{trans} \,.\, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a \in \mathrm{connex} \,.\, R\text{‘‘}\overrightarrow{Q}\text{‘}a \subset C\text{‘}P \,.\, P^2 = P \,.\supset:$
$$\exists !\, \mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R \,.\equiv.\, \mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R = \iota\text{‘}R(PQ)\text{‘}a \,.$$
$$\equiv.\, \mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R = \iota\text{‘}R(\breve{P}Q)\text{‘}a \,.$$
$$\equiv.\, R(PQ)\text{‘}a = R(\breve{P}Q)\text{‘}a$$

Thus $\exists !\, \mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R$ is, in a compact series, the necessary and sufficient condition for the existence of a definite limit of the function as the argument approaches a from below.

Without assuming $P^2 = P$, if x is a member of $\mathrm{os}(P, Q_* \upharpoonright \overrightarrow{Q}\text{‘}a)\text{‘}R$, and if x has no immediate predecessor or successor, so that in the neighbourhood of x the series is compact, we still have $x = R(PQ)\text{‘}a = R(\breve{P}Q)\text{‘}a$ (*234·462).

We next consider $\text{ct}\,(PQ)`R$. By the definition we have

***234·5.** $\vdash : a \,\epsilon\, \text{ct}\,(PQ)`R \,.\equiv.\, R`a \,\epsilon\, \text{os}\,(P, Q_* \upharpoonright \overrightarrow{Q_{po}}`a)`R - C`P_1$

Thus a is an argument for which the function has a single value which has no immediate predecessor or successor in P, and which, in virtue of *234·462, is the limit of the function as the argument approaches a from below (*234·52). The cases when $R`a = B`P$ or $R`a = B`\breve{P}$ require special attention; excluding these cases, we arrive at

***234·51.** $\vdash :: Q \,\epsilon\, \text{trans} \,.\, Q_* \upharpoonright \overrightarrow{Q}`a \,\epsilon\, \text{connex} \,.\, R`a \,\epsilon\, \text{D}`P \cap \text{Ꭰ}`P \,.\supset:.$
$a \,\epsilon\, \text{ct}\,(PQ)`R \,.\equiv: R`a \sim\epsilon\, C`P_1 : R`a \,\epsilon\, P\,(z - w) \,.\supset_{z,w}.$
$(\exists y) \,.\, y \,\epsilon\, \overrightarrow{Q}`a \cap \text{Ꭰ}`R \,.\, R``Q\,(y \mapsto a) \subset P\,(z - w)$

This proposition is analogous to *234·41.

We prove (*234·562) that if P, Q are series, and α is any class of arguments for which all the values belong to $C`P$, and if α has a limit at which the function is continuous from below, then the limit of the function, as the argument increases in α, is the value of the function at the limit of α.

We next consider $\text{contin}\,(PQ)`R$, which is defined as $\text{ct}\,(PQ)`R \cap \text{ct}\,(P\breve{Q})`R$. We show that if P is a series whose field contains $R``\overleftrightarrow{Q}`a$, and $Q$ is transitive, and $Q_* \upharpoonright \overleftrightarrow{Q}`a$ is connected, and $R`a$ is neither $B`P$ nor $B`\breve{P}$, then if $a$ belongs to the class $\text{contin}\,(PQ)`R$, $R`a$ is the limit of the function for the argument a for approaches either from below or from above (*234·62). If P is compact, the converse also holds (*234·63). Our definition of a point of continuity is thus identified with the second form of Dini's definition quoted above. It is identified with the first form by the following proposition: In the circumstances of *234·62, if $R`a \,\epsilon\, \text{D}`P \cap \text{Ꭰ}`P$, we have (*234·64)

$a \,\epsilon\, \text{contin}\,(PQ)`R \,.\equiv: R`a \,\epsilon\, C`P - C`P_1 : R`a \,\epsilon\, P\,(z - w) \,.\supset_{z,w}.$
$(\exists y, y') \,.\, y, y' \,\epsilon\, \text{Ꭰ}`R \,.\, a \,\epsilon\, Q\,(y - y') \,.\, R``Q\,(y \mapsto y') \subset P\,(z - w),$

i.e. a is a point of continuity when, and only when, the value $R`a$ for the argument $a$ is a member of the $P$-series having no immediate predecessor or successor, and if $R`a$ is contained in the interval $P\,(z - w)$, then, however small this interval may be, two arguments y, y' can be found such that a lies between them, and the values for all arguments from y to y' (both included) lie in the interval $P\,(z - w)$.

We end with a few propositions on continuous functions. The last of these (*234·73) states that, if P is a compact series and Q is transitive and connected, then R is continuous with respect to P and Q when, and only when, it has arguments in $C`Q$, and for all such arguments a we have

$$R\,(PQ)`a = R\,(\breve{P}Q)`a = R\,(P\breve{Q})`a = R\,(\breve{P}\breve{Q})`a = R`a,$$

i.e. the value for every argument is the limit for that argument for approaches either from above or from below.

When $x \sim\epsilon \text{D}`P_1$, the above proposition is not necessarily true: it may fail if $x = \min_P`\text{sc}(P, Q)`R$.

It is to be observed that $\text{sc}(P, Q)`R$ and $\text{os}(P, Q)`R$ are functions of P_{po}, so that they are unchanged when P_{po} is substituted for P. Hence the hypothesis $P_{\text{po}} \epsilon \text{Ser}$ is as effective, with regard to them, as the hypothesis $P \epsilon \text{Ser}$. This is stated in the following proposition.

***234·106.** $\vdash . \text{sc}(P, Q)`R = \text{sc}(P_{\text{po}}, Q)`R . \text{os}(P, Q)`R = \text{os}(P_{\text{po}}, Q)`R$ [*234·1]

The remaining propositions of the present number are for the most part immediate consequences of those already proved. In order to obtain, from propositions already proved, propositions concerning the limit of a function as the argument approaches the limit of some class of arguments α, we only have to substitute $Q_* \upharpoonright \alpha$ for Q. In order to obtain the limit of a function as the argument approaches a given term a, we take $Q_* \upharpoonright \overrightarrow{Q}`a$ in place of Q.

NOTE

Whilst every effort has been made to reproduce this book to the highest standard, the poor quality of the previous reprint is unavoidably reflected in this impression.

PREFACE TO VOLUME III

THE present volume continues the theory of series begun in Volume II, and then proceeds to the theory of measurement. Geometry we have found it necessary to reserve for a separate final volume.

In the theory of well-ordered series and compact series, we have followed Cantor closely, except in dealing with Zermelo's theorem (*257—8), and in cases where Cantor's work tacitly assumes the multiplicative axiom. Thus what novelty there is, is in the main negative. In particular, the multiplicative axiom is required in all known proofs of the fundamental proposition that the limit of a progression of ordinals of the second class (*i.e.* applicable to series whose fields have $\aleph_0$ terms) is an ordinal of the second class (cf. *265). In consequence of this fact, a very large part of the recognized theory of transfinite ordinals must be considered doubtful.

Part VI, on the theory of ratio and measurement, on the other hand, is new, though it is a development of the method initiated in Euclid Book V and continued by Burali-Forti*. Among other points in our treatment of quantity to which we wish to draw attention we may mention the following. (1) We regard our quantities as in a generalized sense "vectors," and therefore we regard ratios as holding between *relations*. (2) The hypothesis that the vectors concerned in any context form a *group*, which has generally been made prominent in such investigations, sinks with us into a very subordinate position, being sometimes not verified at all, and at other times a consequence of other more fruitful hypotheses. (3) We have developed a theory of ratios and real numbers which is prior to our theory of measurement, and yet is not purely arithmetical, *i.e.* does not treat ratios as mere couples of integers, but as relations between actual quantities such as two distances or two periods of time. (4) In our theory of "vector families," which are families of the kind to which some form of measurement is

* Cf. Peano's *Formulaire*, I. (1895), pp. 28—57.

applicable, we have been able to develop a very large part of their properties before introducing numbers; thus the theory of measurement results from the combination of two other theories, one a pure arithmetic of ratios and real numbers without reference to vectors, the other a pure theory of vectors without reference to ratios or real numbers. (5) With a view to geometrical applications, we have devoted a special Section to cyclic families, such as the angles about a given point in a given plane.

The theory of measurement developed in Part VI will be required in the next volume for the introduction of coordinates in Geometry.

We have to thank various friends for their kindness in bringing to our notice mistakes and misprints noted in the Errata, both in this and in previous volumes.

CONTENTS OF VOLUME III

SECTION D.

WELL-ORDERED SERIES.

Summary of Section D.

A "well-ordered" series is one which is such that every existent class contained in it has a first term, or, what comes to the same thing, one which is such that every class which has successors has a sequent. We will call a relation in general well-ordered if every existent class contained in its field has one or more minima. Then a well-ordered series is a series which is a well-ordered relation.

Well-ordered series have many important properties not possessed by series in general. A well-ordered series is Dedekindian, except for the fact that it may have no last term; *i.e.* every section having a last term is Dedekindian. A well-ordered series which is not null has a first term, and every term of the series (except the last, if there is one) has an immediate successor. A very important property of well-ordered series is that they obey an extended form of mathematical induction, which we shall call "transfinite induction," namely the following: If σ is a class such that the sequent (if any) of any class contained in σ and in the series is a member of σ, then the whole series is contained in σ. (It will be observed that Λ is contained in σ, and therefore, by $*206{\cdot}14$, $B{`}P$ is a member of σ.) This differs from ordinary mathematical induction by the fact that, instead of dealing with the successors of single terms, it deals with the successors of classes. A closely analogous property, which holds for all well-ordered relations, whether serial or not, is the following. If σ is a class such that, whenever $\overrightarrow{P}{`}x \subset \sigma$, where $x$ is any member of $C{`}P$, x itself belongs to σ, then $C{`}P \subset \sigma$. If P is well-ordered, this property holds for all σ's; and conversely, if this property holds for all σ's, P is well-ordered. Hence this property is equivalent to well-orderedness.

If P is a well-ordered series, $\min_P$ selects one term out of each member of $\mathrm{Cl\,ex}{`}C{`}P$. Hence $C{`}P$, which is $\min_P{``}\mathrm{Cl\,ex}{`}C{`}P$, is a member of the multiplicative class of $\mathrm{Cl\,ex}{`}C{`}P$; hence the multiplicative class of $\mathrm{Cl\,ex}{`}C{`}P$ exists, and therefore the multiplicative class of any class contained in $\mathrm{Cl\,ex}{`}C{`}P$ exists (by $*88{\cdot}22$). It follows that if $s{`}\kappa$ can be well-ordered, and $\Lambda \sim\in \kappa$, the multiplicative class of κ exists; and that, if every class can be

well-ordered, the multiplicative axiom holds. The converse of this latter proposition also holds, as has been proved by Zermelo (cf. $*258$).

Another important set of properties of well-ordered series results from $*208{\cdot}41$ ff. Two ordinally similar well-ordered series can only be correlated in one way; and no proper section of a well-ordered series is ordinally similar to the whole series. (A "proper" section is a section not the whole.)

From the uniqueness of the correlator of two similar well-ordered series, it follows that all the uses of the multiplicative axiom in $*164$ can be avoided if the fields of the relations concerned consist of well-ordered series. *I.e.* taking $*164{\cdot}45$, which is the fundamental proposition in this subject, we have, without assuming the multiplicative axiom,

$$P, Q \in \text{Rel}^2\,\text{excl} \,.\supset :\, \exists\,!\, P \,\overline{\text{smor}}\, Q \cap \text{Rl}`\text{smor} \,.\equiv .\, P \,\text{smor smor}\, Q,$$

whenever $C`P$ and $C`Q$ consist of well-ordered series. Hence, under this hypothesis, the multiplicative axiom disappears from the hypotheses of all the consequences of $*164{\cdot}45$.

Ordinal numbers ($*251$) are defined as the relation-numbers of well-ordered series. (This definition is in accordance with usage: otherwise, there would be no special reason against defining "ordinal numbers" as the relation-numbers of series in general. The relation-numbers of series will be called *serial numbers.*) Sums of an ordinal number of ordinal numbers are ordinal numbers, but products of an ordinal number of ordinal numbers are not in general ordinal numbers. The product of an ordinal number of serial numbers is a serial number, and the product of an ordinal number (not zero) of ordinal numbers other than zero is not zero, *i.e.* a product of ordinal numbers, in which the number of factors is an ordinal number, does not vanish unless one of the factors vanishes. (For relations in general, the corresponding proposition requires the multiplicative axiom.) If ν is an ordinal number, and μ is any serial number, $\mu \exp_r \nu$ (*i.e.* μ^ν as it would naturally be called) is a serial number; but if $\mu > 1$, $\mu \exp_r \nu$ is not an *ordinal* number unless ν is finite.

The theory of sections and segments ($*252$, $*253$) is much simplified for well-ordered series, owing to the fact that every proper section has a sequent. Proper sections are identical with proper segments, and both are identical with $\overrightarrow{P}``C`P$. The series of sections, $\varsigma`P_*$, is $\overrightarrow{P};P \nrightarrow C`P$. The series of segments, $\varsigma`P$, is $\overrightarrow{P};P$ or $\overrightarrow{P};P \nrightarrow C`P$ according as there is or is not a last term of $C`P$. The series of sectional relations, P_ς, is $P \upharpoonright ; \overrightarrow{P} ; P \upharpoonright \text{Ɑ}`P \nrightarrow P$; its domain is $P \upharpoonright `` \overrightarrow{P}``C`P$, and its field is $P \upharpoonright `` \overrightarrow{P}``C`P \cup \iota`P$. If $x \in C`P$, $P \upharpoonright \overrightarrow{P}`x$ is never similar to P.

The theory of greater and less among well-ordered series and ordinal numbers is dealt with in *254 and *255. Cantor has proved, by means of segments, that of any two different ordinal numbers one must be the greater. This is proved by showing that of any two well-ordered series which are not similar, one must be similar to a segment of the other. We define an ordinal number α as *less than* another β if series P and Q can be found such that P is an α and Q is a β and P is similar to some relation contained in Q, but not to Q. It can be proved that all the ordinals less than $\mathrm{Nr}`Q$ belong, one each, to the proper segments of Q. Hence to say that the ordinal number of P is less than that of Q is equivalent to saying that there is a proper segment of Q to which P is similar.

When two series have the same ordinal, they also have the same cardinal, in virtue of *151·18, but the converse does not hold. When the cardinal number of one series is greater than that of the other, so is the ordinal number. When two classes can be well-ordered, any well-ordering will make the one class similar to a part of the other, or the other similar to a part of the one, in virtue of the properties of segments of well-ordered series. Hence of two different cardinals each of which is applicable to classes which can be well-ordered, one must be the greater—a property which cannot be proved concerning cardinals in general.

In *256 we deal with the series of ordinals in order of magnitude. We show that this is a well-ordered series. and that the series of all ordinals of a given type has an ordinal number which is greater than any of the ordinals of the given type. This constitutes the solution of Burali-Forti's paradox concerning the greatest ordinal: there is no greatest ordinal in any one type, and all the ordinals of a given type are surpassed by ordinals of higher types.

*257, *258 and *259 deal with "transfinite induction" and its applications, of which the most important is Zermelo's theorem, namely,

***258·34.** $\vdash :. \mu \sim \epsilon 1 . \supset : S \epsilon \epsilon_\Delta`\mathrm{Cl\,ex}`\mu . \equiv .$
$$(\exists P) . P \epsilon \Omega . C`P = \mu . S = \mathrm{min}_P \upharpoonright \mathrm{Cl\,ex}`\mu$$

where Ω is the class of well-ordered series. This proposition leads to the following:

***258·36.** $\vdash : \mu \epsilon C``\Omega \cup 1 . \equiv . \exists ! \epsilon_\Delta`\mathrm{Cl\,ex}`\mu$

I.e. a class can be well-ordered or is a unit class when, and only when, a selection can be made from its existent sub-classes. Hence we arrive at

***258·37.** $\vdash : \mathrm{Mult\,ax} . \equiv . C``\Omega \cup 1 = \mathrm{Cls}$

I.e. the multiplicative axiom is equivalent to the assumption that every class can be well-ordered or consists of a single member.

The proof of Zermelo's theorem uses an extension to transfinite induction of the ideas of *90 and *91, which is explained in *257.

$*250$. ELEMENTARY PROPERTIES OF WELL-ORDERED SERIES.

Summary of $*250$.

A relation is called "well-ordered" when every existent sub-class of its field has one or more minima. A well-ordered series is defined as a well-ordered relation which is a series. We shall denote the class of well-ordered relations by "Bord," which is an abbreviation for "bene ordinata" or "bien ordonnée." The class of well-ordered series will be denoted by Ω. Thus our definitions are

$$\mathrm{Bord} = \hat{P}(\mathrm{Cl}\,\mathrm{ex}`C`P \subset \text{Ɑ}`\mathrm{min}_P) \quad \mathrm{Df},$$

$$\Omega = \mathrm{Ser} \cap \mathrm{Bord} \quad \mathrm{Df}.$$

Well-ordered relations other than series will be seldom referred to after the present number.

By applying the definition of "Bord" to unit classes, it appears that a well-ordered relation must be contained in diversity ($*250{\cdot}104$). A well-ordered relation is one whose existent upper sections all have minima ($*250{\cdot}102$). Hence by $*211{\cdot}17$,

$*250{\cdot}103$. $\vdash : P \in \mathrm{Bord} . \equiv . P_{\mathrm{po}} \in \mathrm{Bord}$

Hence by $*250{\cdot}104$,

$*250{\cdot}105$. $\vdash : P \in \mathrm{Bord} . \supset . P_{\mathrm{po}} \mathrel{\dot{\subset}} J$

By considering couples, it can be shown ($*250{\cdot}111$) that a well-ordered relation in which no class has more than one minimum is connected; hence by $*204{\cdot}16$ and $*250{\cdot}105$, it is a series. Thus we have

$*250{\cdot}125$. $\vdash : P \in \Omega . \equiv . \mathrm{E}\,!!\, \mathrm{min}_P``\mathrm{Cl}\,\mathrm{ex}`C`P$,

I.e. a well-ordered series is a relation such that every existent sub-class of the field has a unique minimum. This might have been taken as the definition of Ω.

By the definition of Ω we have

$$*250{\cdot}121.\ \vdash :. P \in \Omega . \equiv : P \in \mathrm{Ser} : \alpha \subset C`P . \exists ! \alpha . \supset_\alpha . \mathrm{E}!\,\mathrm{min}_P`\alpha :$$
$$\equiv : P \in \mathrm{Ser} : \exists ! \alpha \cap C`P . \supset_\alpha . \mathrm{E}!\,\mathrm{min}_P`\alpha$$

Applying this to $C`P$ we have

$*250{\cdot}13$. $\vdash : P \in \Omega - \iota`\dot{\Lambda} . \supset . \mathrm{E}!\,B`P$

We have also

$*250{\cdot}141$. $\vdash : P \epsilon \Omega . \supset . P \upharpoonleft \alpha \epsilon \Omega$

$*250{\cdot}17$. $\vdash :. P, Q \epsilon \Omega - \iota`\dot{\Lambda} . \supset : P \text{ smor } Q . \equiv . P \upharpoonleft \text{Ǝ}`P \text{ smor } Q \upharpoonleft \text{Ǝ}`Q$

This proposition justifies the subtraction of $\dot{1}$ from the beginning, and is useful in the theory of segments of well-ordered series.

We have next ($*250{\cdot}2$—$\cdot243$) an important set of propositions on P_1 when $P \epsilon \Omega$. The most useful of these is

$*250{\cdot}21$. $\vdash : P \epsilon \Omega . \supset . \text{D}`P = \text{D}`P_1$

I.e. in a well-ordered series every term except the last (if any) has an immediate successor. (It is not in general the case that every term except the first has an immediate predecessor.) Another useful proposition is

$*250{\cdot}242$. $\vdash : P \epsilon \Omega . \supset . P = P_1 \cup P_1 | P$

The next set of propositions ($*250{\cdot}3$—$\cdot362$) is concerned with "transfinite induction." We have

$*250{\cdot}33$. $\vdash . \Omega = \text{connex} \cap \hat{P} \{\alpha \subset C`P \cap \sigma . \supset_\alpha . \overrightarrow{\text{seq}_P}`\alpha \subset \sigma : \supset_\sigma . C`P \subset \sigma\}$

I.e. a well-ordered series is a connected relation P such that the whole field of P is contained in every class σ which is such that the sequent (if any) of every sub-class of $C`P \cap \sigma$ is a member of σ.

$*250{\cdot}35$. $\vdash . \text{Bord} = \hat{P} \{x \epsilon C`P . \overrightarrow{P}`x \subset \sigma . \supset_x . x \epsilon \sigma : \supset_\sigma . C`P \subset \sigma\}$

I.e. a well-ordered relation is a relation P whose field is contained in every class σ which contains every member of $C`P$ whose predecessors are all contained in $\sigma$. We may say that a property is "transfinitely hereditary" in $P$ if it belongs to the sequents of all classes composed of members of $C`P$ which possess the property. In virtue of $*250{\cdot}33$, if P is well-ordered, every transfinitely hereditary property belongs to every member of $C`P$, and conversely.

Our next set of propositions ($*250{\cdot}4$—$\cdot44$) is concerned with $\dot{\Lambda}$ and couples. We prove that $\dot{\Lambda} \epsilon \Omega$ ($*250{\cdot}4$) and that $x \neq y . \supset . x \downarrow y \epsilon \Omega$ ($*250{\cdot}41$).

$*250{\cdot}5$—$\cdot54$ are concerned with selections. We have

$*250{\cdot}5$. $\vdash : P \epsilon \Omega . \supset .$

$$\text{min}_P \upharpoonright \text{Cl ex}`C`P \epsilon \epsilon_\Delta`\text{Cl ex}`C`P . \iota`C`P = \text{Prod}`\text{Cl ex}`C`P$$

whence

$*250{\cdot}51$. $\vdash : \alpha \epsilon C``\Omega . \supset . \exists ! \epsilon_\Delta`\text{Cl ex}`\alpha$

Observe that $C``\Omega$ is the class of those classes that can be well-ordered. From $*250{\cdot}51$ we deduce

$*250{\cdot}54$. $\vdash : C``\Omega \cup 1 = \text{Cls} . \supset . \text{Mult ax}$

The converse, which is Zermelo's theorem, is proved in $*258$.

*250·6—·67 are concerned with consequences of *208. We show that two well-ordered series cannot have more than one correlator (*250·6); that if P is a well-ordered series, and β is contained in a proper section of P, $P \upharpoonright \beta$ is not similar to P (*250·65); and that if P is any well-ordered relation, and α is any class such that there are terms in $C'P$ which are later than any member of $\alpha \cap C'P$, then P is not similar to $P \upharpoonright \alpha$ (*250·67).

∗250·125. $\vdash : P \epsilon \Omega . \equiv . E !! \min_P``\mathrm{Cl\,ex}`C`P$ [∗250·112·113]

The above proposition might be demonstrated, independently of ∗250·112·113, as follows:

(*a*) If $E !! \min_P``\mathrm{Cl\,ex}`C`P$, it follows that $x \epsilon C`P . \supset . E ! \min_P`\iota`x$, whence $x \epsilon C`P . \supset . \sim(xPx)$, whence $P \mathrel{\mathsf{G}} J$.

(*b*) If $E !! \min_P``\mathrm{Cl\,ex}`C`P$, it follows that

$$x, y \epsilon C`P . x \neq y . \supset . E ! \min_P`(\iota`x \cup \iota`y).$$

whence it follows that

$$xPy . \sim(yPx) . \vee . yPx . \sim(xPy).$$

Hence $$P \epsilon \mathrm{connex} . P^2 \mathrel{\mathsf{G}} J.$$

(*c*) If $E !! \min_P``\mathrm{Cl\,ex}`C`P$ it follows that

$$xPy . yPz . \supset . E ! \min_P`(\iota`x \cup \iota`y \cup \iota`z),$$

whence $xPy \,.\, yPz \,.\, \supset \,.\, \sim(zPx)$,

and by $P^2 \mathrel{\mathsf{G}} J$ (which has just been proved)

$$xPy \,.\, yPz \,.\, \supset \,.\, x \neq z.$$

Hence, since, by (b), $P \in \text{connex}$, we must have

$$xPy \,.\, yPz \,.\, \supset \,.\, xPz, \;\; i.e. \;\; P \in \text{trans}.$$

Hence $\quad E \,!!\, \min_P``\text{Cl ex}`C`P \,.\, \supset \,.\, P \in \text{Ser}.$

Hence the above proposition is obvious.

$[*204{\cdot}47 \,.\, *250{\cdot}13]$

This proposition is useful in connection with the series of segmental relations in a well-ordered series, for the series of proper segmental relations in a well-ordered series is (as will be proved later)

$$P \upharpoonright ; \overrightarrow{P} ; P \upharpoonright \mathrm{G}`P,$$

and this is ordinally similar to $P \upharpoonright \mathrm{G}`P$. Hence, by the above proposition, two well-ordered series which are not null are ordinally similar when, and only when, the series of their segmental relations are ordinally similar.

[*88·37] $\supset : \mathrm{Mult\,ax} :. \supset \vdash .$ Prop

The above proposition states that if every class which is not a unit class is the field of some well-ordered series, then the multiplicative axiom holds. The converse of this proposition has been proved by Zermelo (cf. ∗258·47).

∗250·6. $\vdash : P, Q \epsilon \Omega . P \,\mathrm{smor}\, Q . \supset \therefore P \,\overline{\mathrm{smor}}\, Q \epsilon 1$ [∗208·41 . ∗250·12·1]

This proposition is very useful, since it enables us, when two similar series of similar well-ordered series are given, to pick out the correlators of all the pairs without assuming the multiplicative axiom. *I.e.* given $P, Q \epsilon \mathrm{Rel}^2 \mathrm{excl} . S \epsilon P \,\overline{\mathrm{smor}}\, Q . S \subseteq \mathrm{smor}$, if $N \epsilon C\text{'}Q$, the correlator of $\breve{S}\text{'}N$ and N will be $\iota\text{'}(\breve{S}\text{'}N) \,\overline{\mathrm{smor}}\, N$ if $\breve{S}\text{'}N, N \epsilon \Omega$. This enables us to dispense with the multiplicative axiom in the hypotheses of ∗164·44 and its consequences, whenever the relations concerned have fields whose members are well-ordered series.

∗250·61. $\vdash : P \epsilon \Omega . \supset . P \,\overline{\mathrm{smor}}\, P = \iota\text{'}(I \upharpoonright C\text{'}P)$ [∗208·42]

∗250·62. $\vdash : P \epsilon \mathrm{Bord} . S \epsilon \mathrm{cror}\text{'}P . \supset . \sim (\exists x) . (S\text{'}x) P x$ [∗208·43]

∗250·63. $\vdash : P \epsilon \Omega \cap \mathrm{Cnv}\text{''}\Omega . \supset . \mathrm{Rl}\text{'}P \cap \mathrm{Nr}\text{'}P = \iota\text{'}P$ [∗208·45]

This proposition will be useful in showing that a *finite* series is not similar to any proper part of itself, and is a series which is well-ordered and has a converse which is also well-ordered.

∗250·64. $\vdash : P \epsilon \mathrm{Bord} . S \epsilon \mathrm{cror}\text{'}P . \supset . C\text{'}P \cap p\text{'}\overleftarrow{P}\text{''}\mathrm{D}\text{'}S = \Lambda$ [∗208·46]

In virtue of this proposition, a part of a well-ordered series can only be similar to the whole if the part extends to the end of the series. Thus *e.g.* no proper section of a well-ordered series can be similar to the whole.

∗250·65. $\vdash : P \epsilon \Omega . \alpha \epsilon \mathrm{sect}\text{'}P - \iota\text{'}C\text{'}P . \beta \subset \alpha . \supset . \sim \{P \,\mathrm{smor}\, P \upharpoonright \beta\}$

$\vdash . (1) . (4) . \supset \vdash . \text{Prop}$

This proposition is used in proving that the series of ordinals in order of magnitude is well-ordered (*256·3). We prove first that if $P \epsilon \Omega$, the ordinals up to and including $\text{Nr}'P$ are well-ordered; thence, by the above proposition, it follows that the whole series of ordinals is well-ordered.

$*251$. ORDINAL NUMBERS.

Summary of $*251$.

The name "ordinal numbers" is commonly confined to the relation-numbers of well-ordered series, and will be so confined in what follows. The relation-numbers of series in general are commonly called "order-types*." Thus α is an order-type if $\alpha \in \mathrm{Nr}``\mathrm{Ser}$, and $\alpha$ is an ordinal number if $\alpha \in \mathrm{Nr}``\Omega$. In the present number we shall be concerned with a few of the simpler properties of ordinal numbers and of the sums, products, and powers of well-ordered series.

We put $$\mathrm{NO} = \mathrm{Nr}``\Omega \quad \mathrm{Df},$$
where "NO" stands for "ordinal number."

We prove in this number that any relation similar to a well-ordered relation is well-ordered ($*251 \cdot 11$), and therefore any relation similar to a well-ordered series is a well-ordered series ($*251 \cdot 111$). We prove

$*251 \cdot 132 \cdot 142$. $\vdash : \alpha \in \mathrm{NO} . \equiv . \alpha \dot{+} \dot{1} \in \mathrm{NO} . \equiv . \dot{1} \dot{+} \alpha \in \mathrm{NO}$

$*251 \cdot 15 \cdot 16$. $\vdash . 0_r, 2_r \in \mathrm{NO}$

$*251 \cdot 24$. $\vdash : \alpha, \beta \in \mathrm{NO} . \supset . \alpha \dot{+} \beta \in \mathrm{NO}$

We prove that if P is a well-ordered series of mutually exclusive well-ordered series, $\Sigma`P$ is a well-ordered series ($*251 \cdot 21$); that if $P$ is a well-ordered series of series, $\Pi`P$ is a series ($*251 \cdot 3$); that if P is a series and Q is a well-ordered series, P^Q and $P \exp Q$ are series ($*251 \cdot 42$); that if P, Q are well-ordered series, so is $P \times Q$ ($*251 \cdot 55$), and therefore the product of two ordinal numbers is an ordinal number ($*251 \cdot 56$).

In virtue of the uniqueness of the correlator of two well-ordered series, we have

$*251 \cdot 61$. $\vdash :. P, Q \in \mathrm{Rel}^2 \mathrm{excl} . C`P \subset \Omega . \supset :$
$$\exists ! (P \, \overline{\mathrm{smor}} \, Q) \cap \mathrm{Rl}`\mathrm{smor} . \equiv . P \, \mathrm{smor} \, \mathrm{smor} \, Q$$

whence, without assuming the multiplicative axiom,

* We shall also speak of them as "serial numbers."

***251·621.** $\vdash : C`P \subset \Omega \,.\, \exists ! (P \,\overline{\text{smor}}\, Q) \cap \text{Rl}`\text{smor} \,.\, \supset .$
$$\Sigma \text{Nr}`P = \Sigma \text{Nr}`Q \,.\, \Pi \text{Nr}`P = \Pi \text{Nr}`Q$$

***251·65.** $\vdash : \alpha \in \text{NO} - \iota`\Lambda \,.\, \beta \in \text{NR} \,.\, P \in \beta \,.\, C`P \subset \alpha \,.\, \supset .$
$$\Sigma \text{Nr}`P = \beta \dot{\times} \alpha \,.\, \Pi \text{Nr}`P = \alpha \exp_r \beta$$

Finally, we have propositions (*251·7·71) showing that the existence of an existent Ω in any type is equivalent to the existence of 2_r in that type, and therefore holds for every type of homogeneous relations, except (possibly, so far as our primitive propositions can show) in the type of relations of individuals to individuals.

In virtue of the above proposition, the usual relations of addition to multiplication, and of multiplication to exponentiation, when the summands or the factors are all equal, can be established without the multiplicative axiom, provided the summands, or the factors, are *ordinal* numbers.

$*252$. SEGMENTS OF WELL-ORDERED SERIES.

Summary of $*252$.

The properties of sections and segments are greatly simplified in the case of series which are well-ordered, owing to the fact that every proper section has a sequent, whence it follows that the class of proper sections is $\overrightarrow{P}``C`P$; and this is also the class of proper segments. Hence also the series of proper sections or of proper segments is the series $\overrightarrow{P};P$ ($*252\cdot37$). The series of all sections is $\overrightarrow{P};P \rightarrow\!\!\!\!+ C`P$ ($*252\cdot38$); hence ($*252\cdot381$)

$$\mathrm{Nr}`\varsigma`P_* = \mathrm{Nr}`P \dot{+} \dot{1}.$$

$$\vdash . (3) . (4) . *211\cdot26 . \supset \vdash . \mathrm{Prop}$$

In dealing with sections and segments of well-ordered series, it is necessary to distinguish series with a last term from such as have no last term. If a series has no last term, $C\text{‘}P = P\text{“}C\text{‘}P$, so that $C\text{‘}P \in \mathrm{D}\text{‘}P_\epsilon$. But if a series has a last term, $C\text{‘}P \sim\in \mathrm{D}\text{‘}P_\epsilon$; in this case, $\mathrm{D}\text{‘}P_\epsilon = \overrightarrow{P}\text{“}C\text{‘}P$. Thus $\mathrm{D}\text{‘}P_\epsilon$ is either $\overrightarrow{P}\text{“}C\text{‘}P$ or $\mathrm{sect}\text{‘}P$, according as there is or is not a last term. In either case,

$$\mathrm{sect}\text{‘}P = \overrightarrow{P}\text{“}C\text{‘}P \cup \iota\text{‘}C\text{‘}P,$$

as has been already proved in *252·12.

***252·13.** $\vdash : P \in \Omega . \mathrm{E} ! B\text{‘}\breve{P} . \supset . \mathrm{sect}\text{‘}P - \iota\text{‘}C\text{‘}P = \mathrm{D}\text{‘}P_\epsilon = \overrightarrow{P}\text{“}C\text{‘}P .$

$*253$. SECTIONAL RELATIONS OF WELL-ORDERED SERIES.

Summary of $*253$.

In the present number we shall consider the properties of the relation P_s (defined in $*213$) when $P \in \Omega$. The relation P_s has great importance in this case, owing to the fact (to be proved later) that $\mathrm{Nr}``\mathrm{D}`P_s$ is the class of all ordinals less than $\mathrm{Nr}`P$, and that, if P, Q are any two well-ordered series, either P is similar to a member of $C`Q_s$, or $Q$ is similar to a member of $C`P_s$, whence it follows that of any two unequal ordinals one must be the greater.

The present number consists merely of the more elementary properties of P_s when $P \in \Omega$. The interesting properties connected with greater and less will be treated in the following number.

The most useful propositions of the present number are the following:

$*253\cdot13$. $\vdash : P \in \Omega . \supset . \mathrm{D}`P_s = P \upharpoonright ``\overrightarrow{P}``\text{Ɑ}`P = P \upharpoonright ``\overrightarrow{P}``C`P$

$*253\cdot18$. $\vdash : P \in \Omega . \supset . C`P_s \subset P \upharpoonright ``\overrightarrow{P}``\text{Ɑ}`P \cup \iota`P . C`P_s \subset \Omega$

Instead of $C`P_s \subset P \upharpoonright ``\overrightarrow{P}``\text{Ɑ}`P \cup \iota`P$ we shall have equality, unless $P = \dot{\Lambda}$ ($*253\cdot15$).

$*253\cdot2$. $\vdash : P \in \Omega - 2_r . \supset . \mathrm{Nr}`P_s = \mathrm{Nr}`(P \upharpoonright \text{Ɑ}`P) \dot{+} \dot{1}$

The case when $P \in 2_r$ has to be excluded, because then $P \upharpoonright \text{Ɑ}`P = \dot{\Lambda}$.

$*253\cdot21$. $\vdash : P \in \Omega . \supset . \dot{1} \dot{+} \mathrm{Nr}`P_s = \mathrm{Nr}`P \dot{+} \dot{1}$

This proposition involves $\mathrm{Nr}`P_s = \mathrm{Nr}`P$ when P is finite, but when P is infinite it involves $\mathrm{Nr}`P_s = \mathrm{Nr}`P \dot{+} \dot{1}$ (cf. $*261\cdot38$).

$*253\cdot22$. $\vdash : P \in \Omega . \supset . P_s \upharpoonright \mathrm{D}`P_s \;\mathrm{smor}\; P \upharpoonright \text{Ɑ}`P$

$*253\cdot24$. $\vdash : P \in \Omega . \supset . P_s \in \Omega$

$*253\cdot4$. $\vdash : P \in \Omega - \iota`\dot{\Lambda} . \supset .$

$$C`P_s = \hat{Q}\{(\exists R) . P = Q \mathbin{\Uparrow} R . \mathrm{v} . (\exists x) . P = Q \mathbin{+\!\!\!\to} x\}$$

$*253\cdot421$. $\vdash : P \in \Omega . Q \in \mathrm{D}`P_s . \supset . \sim(Q \;\mathrm{smor}\; P)$

$*253\cdot44$. $\vdash : \alpha, \beta \in \mathrm{NO} - \iota`\Lambda . \beta \neq 0_r . \supset . \alpha \dot{+} \beta \neq \alpha$

This proposition marks a difference between ordinals and cardinals. An ordinal is always increased by the addition of anything at the end, whereas this is (often if not always) not the case with a cardinal if it is reflexive and greater than the addendum. The above proposition ceases to be true if we add β at the beginning instead of the end: $\beta \dotplus \alpha = \alpha$ will be true if α is infinite and $\omega \dot{\times} \beta$ is not greater than α. (For the definition of ω, cf. $*263$.)

$*253{\cdot}45$. $\vdash : \alpha \in \mathrm{NO} - \iota`\Lambda - \iota`0_r . \supset . \alpha \dotplus \dot{1} \neq \alpha$

Similar remarks apply to this proposition as to $*253{\cdot}44$.

$*253{\cdot}46$. $\vdash : P \in \Omega . Q, R \in C`P_s . Q \,\mathrm{smor}\, R . \supset . Q = R$

I.e. no two different sections of a well-ordered series are similar.

It follows from $*253{\cdot}46$ that the series of the ordinals of proper sections of a well-ordered series P is similar to the series of proper sections, and therefore, by $*253{\cdot}22$, to the series P with its first term omitted ($*253{\cdot}463$).

We have next a set of propositions ($*253{\cdot}5$—$\cdot574$) on the circumstances under which $\mathrm{Nr}`P_s = \mathrm{Nr}`P$ and those under which $\mathrm{Nr}`P_s = \mathrm{Nr}`P \dotplus \dot{1}$. As a matter of fact, the former holds when P is finite, the latter when P is infinite. But the distinction of finite and infinite will not be introduced till the next section. In the present number, we prove that (assuming $P \in \Omega$) $\mathrm{Nr}`P_s = \mathrm{Nr}`P$ if $C`P_1 = C`P . \mathrm{E} ! B`\breve{P}$, and if not, then $\mathrm{Nr}`P_s = \mathrm{Nr}`P \dotplus \dot{1}$ ($*253{\cdot}56$). This is proved by using $P_1$ as a correlator. ($P_1$ as a correlator moves every term one place down, except the first, which disappears.) For, if $P \in \Omega$, we have $P_1 ; P = P \upharpoonright \mathrm{D}`P$ ($*253{\cdot}5$); hence we prove $P \upharpoonright C`P_1 \,\mathrm{smor}\, P \upharpoonright \mathrm{D}`P$ ($*253{\cdot}502$), and hence, if $C`P_1 = C`P$, we obtain $P \upharpoonright C`P \,\mathrm{smor}\, P \upharpoonright \mathrm{D}`P$ ($*253{\cdot}503$). Hence by $*253{\cdot}2$ (with special consideration of the case when $P \in 2_r$) we have the two propositions

$*253{\cdot}51$. $\vdash : P \in \Omega . C`P_1 = C`P . \mathrm{E} ! B`\breve{P} . \supset . \mathrm{Nr}`P_s = \mathrm{Nr}`P$

$*253{\cdot}511$. $\vdash : P \in \Omega . C`P_1 = C`P . \sim \mathrm{E} ! B`\breve{P} . \supset .$

$$\mathrm{Nr}`P_s = \mathrm{Nr}`P \dotplus \dot{1} . \mathrm{Nr}`P \upharpoonright C`P = \mathrm{Nr}`P$$

But if there is a term, say x, belonging to $C`P - C`P_1$, use P_1 as a correlator for the predecessors of x; we thus find that, in this case, $P \,\mathrm{smor}\, P \upharpoonright C`P$. Hence, by $*253{\cdot}2$, $\mathrm{Nr}`P_s = \mathrm{Nr}`P \dotplus \dot{1}$.

The hypothesis $C`P_1 = C`P . \mathrm{E} ! B`\breve{P}$ means that there is a last term, and every other term has an immediate successor. This, as we shall prove later, and as is indeed obvious, is equivalent to the assumption that P is finite but not null.

From the above propositions it results immediately that

$*253{\cdot}573$. $\vdash :. P \in \Omega . \supset : C`P_1 = C`P . \mathrm{E} ! B`\breve{P} . \equiv . \dot{1} \dotplus \mathrm{Nr}`P \neq \mathrm{Nr}`P$

Hence it will follow that finite ordinals other than 0_r are those which are increased by the addition of $\dot{1}$ at the beginning. We have also

***253·574.** $\vdash :. P \in \Omega - \iota`\dot{\Lambda} . \supset : \text{Ɑ}`P_1 = \text{Ɑ}`P . E ! B`\breve{P} . \equiv . \dot{1} \dot{+} \mathrm{Nr}`P = \mathrm{Nr}`P \dot{+} \dot{1}$

Whence it will follow that finite ordinals are those for which the addition of $\dot{1}$ is commutative.

If α is any ordinal number, and $P \in \alpha$, the ordinal numbers of the sectional relations of P are all those ordinals which can be made equal to α by being added to, *i.e.* all ordinals β such that, for a suitable γ, $\alpha = \beta \dotplus \gamma$. (Here γ must be an ordinal or $\dot{1}$.) Further, in virtue of $*250 \cdot 67$, no member of $\mathrm{D}'P_s$ is similar to P; hence, if α is an ordinal, and $\alpha = \beta \dotplus \gamma$, where $\gamma \neq 0_r$, it follows that $\alpha \neq \beta$. (Observe that $\alpha \neq \gamma$ does not follow from $\beta \neq 0_r . \alpha = \beta \dotplus \gamma$.) These and kindred propositions, which are important in the theory of ordinals, are now to be proved.

[*253·401·13]

The following propositions are concerned in proving that $\mathrm{Nr}\text{‘}P_s$ is either $\mathrm{Nr}\text{‘}P$ or $\mathrm{Nr}\text{‘}P \dot{+} \dot{1}$. This is proved by using P_1 as a correlator. The methods employed anticipate the discussion of finite and infinite series; in fact, when P is finite, $\mathrm{Nr}\text{‘}P_s = \mathrm{Nr}\text{‘}P$, and when P is infinite, $\mathrm{Nr}\text{‘}P_s = \mathrm{Nr}\text{‘}P \dot{+} \dot{1}$. But it is important at this stage to know that $\mathrm{Nr}\text{‘}P_s$ is either equal to or greater than $\mathrm{Nr}\text{‘}P$, and the propositions are therefore inserted here.

This proposition shows that if P is a well-ordered series in which every term except the first has an immediate predecessor, the series obtained by omitting the last term (if any) is similar to that obtained by omitting the first term. The converse also holds, as will be shown later. The hypothesis $P \in \Omega . \text{C}'P_1 = \text{C}'P$ is equivalent to the hypothesis that P is finite or a progression. (Here a *progression* is not what was defined as "Prog" in *121, but what Cantor calls ω; *i.e.* if $R \in$ Prog, R_{po} is a progression in our present sense.)

$*254$. GREATER AND LESS AMONG WELL-ORDERED SERIES.

Summary of $*254$.

In the present number we have to prove that of any two well-ordered series one must be similar to a sectional relation of the other. From this it will follow that of any two unequal ordinals one must be the greater. The propositions of the present number are due to Cantor*.

Our procedure is as follows. We define a relation "$RP_{\mathrm{sm}}Q$," meaning "R is a proper section of P, and is similar to Q," *i.e.*

$$RP_{\mathrm{sm}}Q \,.\equiv.\, R \in \mathrm{D}`P_\varsigma \,.\, R \,\mathrm{smor}\, Q.$$

In virtue of $*253{\cdot}46$, if $P, Q \in \Omega$, $P_{\mathrm{sm}} \in 1 \rightarrow \mathrm{Cls}$ ($*254{\cdot}22$) and $P_{\mathrm{sm}} \upharpoonright \mathrm{D}`Q_\varsigma \in 1 \rightarrow 1$ ($*254{\cdot}222$). Thus if $S$ is any proper section of $Q$ which is similar to some proper section of $P_\varsigma$, the proper section of $P$ to which it is similar is $P_{\mathrm{sm}}`S$. It is easy to prove that $P_{\mathrm{sm}} ; Q_\varsigma \mathbin{\text{⁅}} \mathrm{D}`Q_\varsigma$ is a section of $P$; and if $\mathrm{D}`P_\varsigma \subset \text{ᗡ}`Q_{\mathrm{sm}}$, *i.e.* if every proper section of P is similar to some proper section of Q, we shall have ($*254{\cdot}261$)

$$P_\varsigma \mathbin{\text{⁅}} \mathrm{D}`P_\varsigma = P_{\mathrm{sm}} ; Q_\varsigma \mathbin{\text{⁅}} \mathrm{D}`Q_\varsigma.$$

Hence it follows ($*254{\cdot}27$) that if, further, $\mathrm{D}`Q_\varsigma \subset \text{ᗡ}`P_{\mathrm{sm}}$, we shall have

$$P_\varsigma \mathbin{\text{⁅}} \mathrm{D}`P_\varsigma \,\mathrm{smor}\, Q_\varsigma \mathbin{\text{⁅}} \mathrm{D}`Q_\varsigma,$$

i.e. by $*253{\cdot}25$, $\qquad P \,\mathrm{smor}\, Q \quad (*254{\cdot}31)$.

Thus (A) if every proper section of P is similar to some proper section of Q, and vice versa, then P is similar to Q.

Consider next the case in which every proper section of P is similar to a proper section of Q (*i.e.* $\mathrm{D}`P_\varsigma \subset \text{ᗡ}`Q_{\mathrm{sm}}$), but not vice versa, so that $\exists ! \mathrm{D}`Q_\varsigma - \text{ᗡ}`P_{\mathrm{sm}}$. It is easy to prove that, under this hypothesis, if $S \in \mathrm{D}`Q_\varsigma - \text{ᗡ}`P_{\mathrm{sm}}$, then $\mathrm{D}`P_\varsigma \subset \text{ᗡ}`S_{\mathrm{sm}}$ ($*254{\cdot}32$). But if S is the minimum (in the order Q_ς) of the class $\mathrm{D}`Q_\varsigma - \text{ᗡ}`P_{\mathrm{sm}}$, then $\mathrm{D}`S_\varsigma \subset \text{ᗡ}`P_{\mathrm{sm}}$. Hence, by (A),

$$S \,\mathrm{smor}\, P \quad (*254{\cdot}321).$$

Thus (B) if every proper section of P is similar to a proper section of Q, but not vice versa, then P is similar to a proper section of Q ($*254{\cdot}33$).

* *Math. Annalen*, Vol. 49.

From (B), by transposition, we find that if every proper section of P is similar to a proper section of Q, but P itself is not similar to any proper section of Q, then every proper section of Q is similar to a proper section of P, whence, by (A), P is similar to Q (*254·34). Hence, if there are proper sections of P which are not similar to any proper section of Q, the smallest of such sections (say P') must be similar to Q, since it is not itself similar to any proper section of Q, but all its proper sections are similar to proper sections of Q. Hence (C) if there are proper sections of P which are not similar to any proper section of Q, then there is a proper section of P which is similar to Q, *i.e.*

$$\vdash : P, Q \epsilon \Omega \,.\, \exists ! \, \mathrm{D}`P_\varsigma - \mathrm{G}`Q_{\mathrm{sm}} \,.\, \supset \,.\, Q \epsilon \mathrm{G}`P_{\mathrm{sm}} \quad (*254·35).$$

Thus either (1) $\exists ! \, \mathrm{D}`P_\varsigma - \mathrm{G}`Q_{\mathrm{sm}}$, in which case $Q \epsilon \mathrm{G}`P_{\mathrm{sm}}$, or (2) $\exists ! \, \mathrm{D}`Q_\varsigma - \mathrm{G}`P_{\mathrm{sm}}$, in which case $P \epsilon \mathrm{G}`Q_{\mathrm{sm}}$, or (3) $\mathrm{D}`P_\varsigma \subset \mathrm{G}`Q_{\mathrm{sm}}$ and $\mathrm{D}`Q_\varsigma \subset \mathrm{G}`P_{\mathrm{sm}}$, in which case, by (A), $P \,\mathrm{smor}\, Q$. Thus (D) if P and Q are any two well-ordered series, either they are similar or one is similar to a proper section of the other (*254·37).

We now proceed to define one well-ordered series P as *less than* another well-ordered series Q if P is similar to a part of Q, but not to Q, *i.e.* we put

$$\mathrm{less} = \hat{P}\hat{Q} \{P, Q \epsilon \Omega \,.\, \exists ! \, \mathrm{Rl}`Q \cap \mathrm{Nr}`P \,.\, \sim (P \,\mathrm{smor}\, Q)\} \quad \mathrm{Df.}$$

(Observe that we have $\mathrm{Rl}`Q$ in this definition, not $\mathrm{D}`Q_\varsigma$.)

It follows from (D) that, P and Q being well-ordered series, if P and Q are not similar, one must be less than the other (*254·4). It follows also from *250·65 that if P is similar to a proper section of Q Q cannot be less than P (*254·181). Hence P is less than Q when, and only when, P is similar to a proper section of Q, *i.e.*

$$P \,\mathrm{less}\, Q \,.\, \equiv \,.\, P, Q \epsilon \Omega \,.\, P \epsilon \mathrm{G}`Q_{\mathrm{sm}} \quad (*254·41).$$

Hence if each of two well-ordered series is similar to a part of the other, the two series are similar (*254·45); and in any other case, one of them is similar to a proper section of the other.

From the above results we easily obtain the following propositions, which are useful in the ordinal theory of finite and infinite.

***254·51.** $\vdash : P \,\mathrm{less}\, Q \,.\, \equiv \,.\, P, Q \epsilon \Omega \,.\, \mathrm{Rl}`P \cap \mathrm{Nr}`Q = \Lambda$

I.e. one well-ordered series is less than another when, and only when, no part of it is similar to the other.

***254·52.** $\vdash : P \epsilon \Omega \,.\, \alpha \subset C`P \,.\, \exists ! \, C`P \cap p`\overleftarrow{P}``\alpha \,.\, \supset \,.\, P \upharpoonright \alpha \,\mathrm{less}\, P$

I.e. any part of a well-ordered series which stops short of the end is less than the whole series

$*254{\cdot}55.\quad \vdash :. \, Q \,\text{less}\, P \,.\equiv: P, Q \in \Omega :(\exists R) \,.\, R \,\text{smor}\, Q \,.\, R \Subset P \,.\, \exists ! \, C\text{‘}P \cap p\text{‘}\overleftarrow{P}\text{“}C\text{‘}R$

I.e. one well-ordered series is less than another when, and only when, it is similar to a part of the other which stops short of the end.

$*254{\cdot}01.\quad \text{less} = \hat{P}\hat{Q}\{P, Q \in \Omega \,.\, \exists ! \, \text{Rl}\text{‘}Q \cap \text{Nr}\text{‘}P \,.\, \sim (P \,\text{smor}\, Q)\} \quad \text{Df}$

$\vdash . (1) . (2) . *254·261 . *151·22 . \supset \vdash .$ Prop

In virtue of the above proposition, we have, when its hypothesis is realized,

$$(Q_s \upharpoonright \mathrm{D}`Q_s) \,\mathrm{smor}\, (P_s \upharpoonright \mathrm{D}`P_s),$$

whence, by *253·25, $\quad Q \,\mathrm{smor}\, P$.

This proposition is the converse of *254·141.

In the above proposition we take $Q_{sm} \upharpoonright C`(P_s \upharpoonright \mathrm{D}`P_s)$ as the correlator, rather than $Q_{sm} \upharpoonright \mathrm{D}`P_s$, so as not to have to make an exception for the case when $P \epsilon 2_r$. For if $P \epsilon 2_r$, $\mathrm{D}`P_s \epsilon 1$, but $P_s \upharpoonright \mathrm{D}`P_s = \dot{\Lambda}$. Thus $Q_{sm} \upharpoonright \mathrm{D}`P_s$ is not a correlator in this case.

The following propositions, down to the end of the present number, are important, and give the foundations of the theory of inequality between well-ordered series and between ordinals.

The relation "less" fails to generate a series, because it is not connected, two similar well-ordered series being neither greater nor less than each other. On the other hand, the relation Nr⁏less is serial, since two similar well-ordered series both contribute the same term to the field of Nr⁏less, and therefore connection does not fail. The relation Nr⁏less will be dealt with in the next number.

In order to obtain $C`\text{less} = \Omega$, we need, as appears from (1) in the above proof, $\exists ! \Omega - \iota`\dot{\Lambda}$. In virtue of $*251\cdot7$, this requires $\exists ! 2$. By $*101\cdot42\cdot43$, this holds if "less" has its field defined as belonging to a class-type or a relation-type. If, however, "less" has its field defined as composed of individuals, the primitive propositions assumed in the present work do not enable us to prove $\exists ! 2$, nor therefore to prove $\dot{\exists} ! \text{less}$.

It should be observed that "less," like "sm" and "smor," is significant when it is not homogeneous; but "$C`$less" is only significant for homogeneous typical determinations of "less," because only homogeneous relations have fields.

*255. GREATER AND LESS AMONG ORDINAL NUMBERS.

Summary of *255.

If P and Q are well-ordered series, we say that $\text{Nr}'P$ is less than $\text{Nr}'Q$ if P is less than Q. Thus if μ and ν are ordinal numbers, we say that μ is less than ν if there are well-ordered series P, Q, such that $\mu = \text{Nr}'P$ and $\nu = \text{Nr}'Q$ and P is less than Q. In order to exclude the case where, in the type concerned, we have $\text{Nr}'P = \Lambda$ or $\text{Nr}'Q = \Lambda$, we assume $\mu = \text{N}_0\text{r}'P$ and $\nu = \text{N}_0\text{r}'Q$. Thus we put

$$\mu \lessdot \nu \,.\equiv.\, (\exists P, Q) \,.\, \mu = \text{N}_0\text{r}'P \,.\, \nu = \text{N}_0\text{r}'Q \,.\, P \,\text{less}\, Q,$$

i.e. we put $$\lessdot = \text{N}_0\text{r}{;}\text{less} \quad \text{Df.}$$

In order to be able to speak of $\text{Nr}'P$ (where the type of "Nr" is left ambiguous) as greater or less than $\text{Nr}'Q$, we put

$$\mu \lessdot \text{Nr}'P \,.=.\, \mu \lessdot \text{N}_0\text{r}'P \quad \text{Df,}$$

$$\text{Nr}'P \lessdot \mu \,.=.\, \text{N}_0\text{r}'P \lessdot \mu \quad \text{Df.}$$

The treatment of types proceeds, mutatis mutandis, as in *117, to which, together with the prefatory statement in Vol. II, the reader is referred for explanations.

In virtue of *254·46 and *117·1, there is a close analogy between cardinal and ordinal inequality. That is to say, most of the properties of cardinal inequality have exact analogues for ordinal inequality, and these analogues have analogous proofs. (In the present number, when a proposition is analogous to the proposition with the same decimal part in *117, and has an analogous proof, we shall omit the proof.) But ordinal inequality has a good many properties which have no analogues for cardinal inequality. The chief of these, upon which most of the rest depend, is

***255·112.** $\vdash :. \mu, \nu \in \text{N}_0\text{O} \,.\supset:\, \mu \lessdot \nu \,.\vee.\, \mu = \text{smor}``\nu \,.\vee.\, \nu \lessdot \mu$

where "N_0O" stands for "homogeneous ordinals," *i.e.* $\text{NO} \cap \text{N}_0\text{R}$. We have also, what is often important,

***255·17.** $\vdash : \text{Nr}'P \gtrdot \text{Nr}'Q \,.\equiv.\, Q \,\text{less}\, P \,.\equiv.\, P, Q \in \Omega \,.\, Q \in \text{Cl}'P_{\text{sm}} \,.$
$$\equiv.\, P, Q \in \Omega \,.\, \exists \,!\, \text{D}'P_{\text{s}} \cap \text{Nr}'Q$$

so that

***255·171.** $\vdash :. P \in \Omega . \supset : \mu \lessdot \mathrm{Nr}'P . \equiv . \mu \in \mathrm{Nr}``\mathrm{D}'P_\varsigma - \iota'\Lambda$

and more generally,

***255·172.** $\vdash :. P \in \Omega . \supset :$

$$\mu \lessdot \mathrm{Nr}'P . \equiv . (\exists \alpha) . \alpha \subset C'P . \exists ! C'P \cap p'\overleftarrow{P}``\alpha . \mu = \mathrm{Nr}'P \upharpoonright \alpha . \exists ! \mu$$

As in cardinals, μ is greater than ν if (and only if) μ is the sum of ν and an ordinal other than zero, including $\dot{1}$ except when $\nu = 0_r$ (*255·33). But it is necessary to the truth of this proposition that the addendum should come after ν, not before it; *i.e.* $\nu \dotplus \varpi \gtrdot \nu$ unless $\varpi = 0_r$ (*255·32·321), but $\varpi \dotplus \nu$ is often equal to ν.

If α, β, γ are ordinals, and $\alpha \gtrdot \beta$, we shall have

$$\gamma \dotplus \alpha \gtrdot \gamma \dotplus \beta \quad (*255·561),$$

$$\alpha \dot{\times} \beta \gtrdot \beta \text{ if } \alpha \neq 0_r . \beta \neq 0_r \quad (*255·571),$$

$$\alpha \dot{\times} \gamma \gtrdot \beta \dot{\times} \gamma \text{ if } \gamma \neq 0_r \quad (*255·58),$$

$$\gamma \dot{\times} \beta \gtrdot \gamma \text{ if } \gamma \text{ is of the form } \delta \dotplus \dot{1} \quad (*255·573),$$

$$\gamma \dot{\times} \alpha \gtrdot \gamma \dot{\times} \beta \text{ if } \gamma \text{ is of the form } \delta \dotplus \dot{1} \quad (*255·582).$$

From the above propositions it follows that if α, β, γ are ordinals,

$$\gamma \dotplus \alpha = \gamma \dotplus \beta . \supset . \alpha = \beta$$

(*255·565, where β may be substituted for smor$``\beta$ whenever significance permits; cf. note to *120·51), which gives the uniqueness of subtraction from the end (subtraction from the beginning is not unique);

$$\alpha \dot{\times} \gamma = \beta \dot{\times} \gamma . \supset . \alpha = \beta \text{ unless } \gamma = 0_r \quad (*255·59).$$

which gives the uniqueness of division by an end-factor;

$$\gamma \dot{\times} \alpha = \gamma \dot{\times} \beta . \supset . \alpha = \beta \text{ if } \gamma = \delta \dotplus \dot{1} \quad (*255·591),$$

which gives the uniqueness of division by a beginning-factor of the form $\delta \dotplus \dot{1}$.

We do not have generally

$$\alpha, \beta, \gamma \in \mathrm{N_0O} . \alpha \lessdot \beta . \supset . \alpha \exp_r \gamma \lessdot \beta \exp_r \gamma,$$

because $\alpha \exp_r \gamma$ and $\beta \exp_r \gamma$ are in general not *ordinal* numbers, since series having these numbers are in general not well-ordered. Thus the theory of ordinal inequality has only a restricted application to exponentiation. This subject cannot be adequately dealt with until we have considered finite and infinite series.

If α is an ordinal, $C``\alpha$ is the corresponding cardinal, *i.e.* the cardinal number of terms in a series whose ordinal number is α. Thus the cardinal numbers of classes which can be well-ordered are $C```\mathrm{NO}$, *i.e.*

***255·7.** $\vdash . \mathrm{Nc}``C``\Omega = C```\mathrm{NO}$

It is evident that

***255·71.** $\vdash : P \,\text{less}\, Q \,.\supset .\, \text{Nc}`C`P \leqslant \text{Nc}`C`Q$

whence, by *254·4,

***255·73.** $\vdash :. P, Q \,\epsilon\, \Omega \,.\supset :$

$$\text{Nc}`C`P < \text{Nc}`C`Q \,.\vee .\, \text{Nc}`C`P = \text{Nc}`C`Q \,.\vee .\, \text{Nc}`C`P > \text{Nc}`C`Q$$

whence also

***255·74.** $\vdash :. \alpha, \beta \,\epsilon\, C``\text{NO} - \iota`\Lambda \,.\supset : \alpha \leqslant \beta \,.\vee .\, \alpha > \beta$

Thus if two classes can both be well-ordered, they either have the same cardinal, or the cardinal of one is less than that of the other

We have

***255·75.** $\vdash : P\ Q \,\epsilon\, \Omega \,.\, \text{Nc}`C`P < \text{Nc}`C`Q \,.\supset .\, P \,\text{less}\, Q$

or, what comes to the same thing,

***255·76.** $\vdash : \alpha, \beta \,\epsilon\, \text{NO} \,.\, C``\alpha < C``\beta \,.\supset .\, \alpha \lessdot \beta$

The converse of this proposition only holds for finite ordinals. If α is an infinite ordinal, $\alpha \dot{+} \dot{1}$ always exists and is greater than α, but $C``\alpha = C``(\alpha \dot{+} \dot{1})$. (The existence of $\alpha \dot{+} \dot{1}$ is deduced from that of α by taking a member of α, and removing its first term to the end. The result is a series whose number is $\alpha \dot{+} \dot{1}$, in virtue of *253·503·54.)

***255·01.** $\lessdot = \text{N}_0\text{r}`\text{less}$ Df

***255·02.** $\gtrdot = \text{Cnv}`\lessdot$ Df

***255·03.** $\text{N}_0\text{O} = \text{NO} \cap \text{N}_0\text{R}$ Df

Thus "N_0O" means "homogeneous ordinals." In virtue of *155·34·22, this is the same as "ordinals other than Λ." It is not, however, strictly correct to put $\text{N}_0\text{O} = \text{NO} - \iota`\Lambda$, because if the "NO" on the right is derived from an ascending Nr, it will not contain all the ordinals in the type to which it takes us, but only those which are not too big to be derived from the lower type from which "Nr" starts. Thus in this case N_0O will be a larger class than $\text{NO} - \iota`\Lambda$. If, however, the "Nr" from which the "NO" on the right is derived is homogeneous or descending, we shall have

$$\text{N}_0\text{O} = \text{NO} - \iota`\Lambda.$$

***255·04.** $\leqslant = \lessdot \cup \text{smor}_\epsilon \upharpoonright \text{N}_0\text{O}$ Df

This definition leads to the usual meaning of "less than or equal to." We want the relation "less than or equal to" to hold only between numbers of the sort in question (cardinal or ordinal), and we want "equal to" to hold between two numbers which are merely different typical determinations of a given number, provided neither of these typical determinations is Λ. That is, if μ is an ordinal which is not Λ, $\text{smor}``\mu$ is to be reckoned equal to $\mu$ in every type in which it is not $\Lambda$. Thus if $\nu = \text{smor}``\mu$, *i.e.* if $\nu = \text{smor}_\epsilon`\mu$, we

shall reckon ν equal to μ if both are ordinals and neither is Λ, *i.e.* in virtue of $*155{\cdot}34{\cdot}22$, if $\mu, \nu \in \mathrm{N_0O}$. This leads to the above definition.

$*255{\cdot}05.\quad \geqslant\, = \mathrm{Cnv}`\leqslant \qquad$ Df

$*255{\cdot}06.\quad \mu < \mathrm{Nr}`P \,.=.\, \mu < \mathrm{N_0r}`P \quad$ Df

On this definition, compare the remarks on $*117{\cdot}02$.

$*255{\cdot}07.\quad \mathrm{Nr}`P < \mu \,.=.\, \mathrm{N_0r}`P < \mu \quad$ Df

The following propositions (down to $*255{\cdot}108$) merely re-state the above definitions.

$*255{\cdot}1.\quad \vdash : \mu < \nu \,.\equiv.\, (\exists P, Q) \,.\, \mu = \mathrm{N_0r}`P \,.\, \nu = \mathrm{N_0r}`Q \,.\, P \text{ less } Q$

$\equiv.\, P, Q \in \Omega \,.\, \sim (\mathrm{Nr}`Q \leqslant \mathrm{Nr}`P)$ [*255·115]

***255·291.** $\vdash : \mu < \nu \,.\equiv.\, \mu \leqslant \nu \,.\, \sim (\nu \leqslant \mu) \,.\equiv.\, \mu, \nu \in \mathrm{N_0O} \,.\, \sim (\nu \leqslant \mu)$ [*255·114]

In the following proposition, we employ an abbreviation which is justified by its convenience, namely we put

$$(\exists \varpi) \,.\, \varpi \in \mathrm{NO} \cup \iota`\dot{1} \,.\, \mathrm{Nr}`P = \mathrm{Nr}`Q \dotplus \varpi$$

instead of

$$(\exists \varpi) \,.\, \varpi \in \mathrm{NO} \,.\, \mathrm{Nr}`P = \mathrm{Nr}`Q \dotplus \varpi \,.\vee.\, \mathrm{Nr}`P = \mathrm{Nr}`Q \dotplus \dot{1}.$$

In virtue of *51·239, these two expressions would be equivalent if $\dot{1}$ had any independent meaning; but as $\dot{1}$ is only significant as an addendum, *51·239 cannot be applied. We will, however, adopt the following definitions:

***255·298.** $(\exists \varpi) \,.\, \varpi \in \kappa \cup \iota`\dot{1} \,.\, f(\mu \dotplus \varpi) \,.=:\, (\exists \varpi) \,.\, \varpi \in \kappa \,.\, f(\mu \dotplus \varpi) \,.\vee.\, f(\mu \dotplus \dot{1})$ Df

***255·299.** $\varpi \in \kappa \cup \iota`\dot{1} \,.\supset_\varpi.\, f(\mu \dotplus \varpi) \,.=:\, \varpi \in \kappa \,.\supset_\varpi.\, f(\mu \dotplus \varpi) : f(\mu \dotplus \dot{1})$ Df

These definitions enable us to state many propositions, in which $\dot{1}$ occurs, as though $\dot{1}$ were an ordinal number.

***255·3.** $\vdash :. \mathrm{Nr}'P \geqslant \mathrm{Nr}'Q . \equiv : P, Q \in \Omega : (\exists \varpi) . \varpi \in \mathrm{NO} \cup \iota'\dot{1} . \mathrm{Nr}'P = \mathrm{Nr}'Q \dot{+} \varpi$

This proposition establishes the uniqueness of subtraction from the end. Owing to the fact that ordinal addition is not commutative, we have to distinguish "subtraction from the end" from "subtraction from the beginning." They may be called *terminal* and *initial* subtraction respectively. Thus by the above proposition, *terminal* subtraction among ordinals is unique. This does not hold in general for *initial* subtraction among ordinals.

***255·565.** $\vdash : \alpha, \beta, \gamma \in N_0O . \gamma \dot{+} \alpha = \gamma \dot{+} \beta . \supset . \alpha = \text{smor}``\beta$ [*255·564]

The above proposition is still true if we put $\alpha = \beta$ instead of $\alpha = \text{smor}``\beta$ in the conclusion, but in that case it is only significant when α and β are of the same type, whereas in the above form it is free from this limitation.

The following propositions are concerned with the relations of ordinals to the corresponding cardinals, *i.e.* to the cardinals of the fields of well-ordered series having the given ordinals. If P is a well-ordered series whose ordinal is α, $C``\alpha = \mathrm{Nc}'C'P$, so that $C``\alpha$ is a cardinal whose members can be well-ordered. Such cardinals have the property that of any two which are not equal, one must be the greater.

If the cardinal number of one series is greater than that of another, so is the ordinal number; but the converse does not hold except for finite numbers.

*256. THE SERIES OF ORDINALS.

Summary of *256.

In the present number, we have to consider the series of ordinals in order of magnitude. Propositions on this subject deserve close attention, because it is in this connection that Burali-Forti's paradox* arises. This paradox, as we shall show in the present number, is avoided by the doctrine of types. But before discussing the paradox, it will be well to explain various propositions which raise no difficulty.

For convenience of notation, we shall, in the present number, employ the letter M for the relation "$<$" (This letter is chosen as the initial of "minor.") Thus "$\alpha M \beta$" means that α and β are ordinals of which α is less than β. $\overrightarrow{M}{}^{\text{‘}}\beta$ will be the class of ordinals less than β, $\breve{M}_1{}^{\text{‘}}\beta$ will be $\beta \dot{+} \dot{1}$, and $M_1{}^{\text{‘}}\beta$, when it exists, will be such that either $M_1{}^{\text{‘}}\beta \dot{+} \dot{1} = \beta$, or $\beta = 2_r \,.\, M_1{}^{\text{‘}}\beta = 0_r$. Thus $\text{Ɑ}{}^{\text{‘}}M_1$ is the class of ordinals having immediate predecessors, and $\overrightarrow{B}{}^{\text{‘}}M_1$ is the class of ordinals not having immediate predecessors.

We have (*256·12)

$$\vdash :.\ \alpha M \beta \,.\equiv :\ \alpha, \beta \in \mathrm{N_0 O} : (\exists \gamma) \,.\, \gamma \in \mathrm{NO} - \iota{}^{\text{‘}}0_r \cup \iota{}^{\text{‘}}\dot{1} \,.\, \beta = \alpha \dot{+} \gamma,$$

that is, one ordinal is less than another when something not zero can be added to the first to make it equal to the second;

***256·11.** $\vdash : P \in \Omega \,.\supset .\, \overrightarrow{M}{}^{\text{‘}}\mathrm{Nr}{}^{\text{‘}}P = \mathrm{Nr}{}^{\text{‘‘}}\mathrm{D}{}^{\text{‘}}P_s$

I.e. the numbers less than that of P are the numbers of the proper segments of P. Also, if $P \in \Omega$,

$$M \upharpoonright \overrightarrow{M}{}^{\text{‘}}\mathrm{Nr}{}^{\text{‘}}P = \mathrm{N_0 r} ; (P_s \upharpoonright \mathrm{D}{}^{\text{‘}}P_s) \,.\, \mathrm{N_0 r} \upharpoonright \mathrm{D}{}^{\text{‘}}P_s \in 1 \to 1 \quad (*256{\cdot}2{\cdot}201),$$

so that (*256·202) the series of ordinals less than that of P is similar to the series of the proper segments of P, *i.e.* to $P \upharpoonright \text{Ɑ}{}^{\text{‘}}P$ (in virtue of *253·22). It follows (*256·22) that every section of M is well-ordered, and therefore that M is well-ordered (*256·3), *i.e.* that the ordinals in order of magnitude form a well-ordered series.

* "Una questione sui numeri transfiniti," *Rendiconti del circolo matematico di Palermo*, Vol. XI. (1897).

For the purposes of the present number, it is convenient to include 1_s (cf. *153) in the series of ordinals; we therefore get

$$N = M \cup 0_r \downarrow 1_s \cup (\iota`1_s) \uparrow \text{C}`M \quad \text{Dft [*256]}.$$

The effect of this definition is merely to insert 1_s in the series M between 0_r and 2_r. We then have (*256·42)

$$\text{Nr}`N = \dot{1} \dotplus \text{Nr}`M.$$

Now if $P \epsilon \Omega$, $P \upharpoonright \text{C}`P$ (as we have just seen) is similar to a proper segment of M, so that if we omit to mention types we obtain

$$\vdash : P \epsilon \Omega . \supset . \text{Nr}`P \upharpoonright \text{C}`P < \text{Nr}`M.$$

Hence $\text{Nr}`P$, which is $\dot{1} \dotplus \text{Nr}`P \upharpoonright \text{C}`P$, is less than $\dot{1} \dotplus \text{Nr}`M$ (by *255·63), *i.e.* is less than N. Hence

$$\vdash : P \epsilon \Omega . \supset . \text{Nr}`P < \text{Nr}`N.$$

Nevertheless $N \epsilon \Omega$, so that it might seem as if $\text{Nr}`N$ must be less than itself, which is impossible by *255·42. Hence we are led to Burali-Forti's paradox concerning the ordinal number of all ordinals.

Burali-Forti's own statement of his paradox, which is somewhat different from the above, may be summarized as follows. Assuming

$$\alpha, \beta \epsilon \text{N}_0\text{O} . \supset : \alpha < \beta . \text{v} . \alpha = \beta . \text{v} . \alpha > \beta \qquad \text{(A)},$$

we shall have $\qquad \alpha \epsilon \text{N}_0\text{O} . \supset . \alpha < \alpha \dotplus \dot{1}.$

But we also have $\qquad \alpha \epsilon \text{N}_0\text{O} . \supset . \alpha \leqslant \text{Nr}`N.$

Hence $\qquad \text{Nr}`N < \text{Nr}`N \dotplus \dot{1} . \text{Nr}`N \dotplus \dot{1} \leqslant \text{Nr}`N,$

which is impossible. The conclusion drawn by Burali-Forti is that the above proposition (A) is false. This, however, cannot be maintained in view of Cantor's proof, reproduced above (*255·112, depending on *254·4). The solution of the paradox must therefore be sought elsewhere.

With regard to Burali-Forti's statement of the paradox, it is to be observed that "$\alpha < \alpha \dotplus \dot{1}$" only holds if $\exists ! \alpha \dotplus \dot{1}$, *i.e.* if $(\exists P) . P \epsilon \alpha . C`P \neq \text{V}$. This will always hold if $\alpha$ exists and is infinite, because then, if $P \epsilon \alpha$, $P \upharpoonright \text{C}`P \rightarrow B`P \epsilon \alpha \dotplus \dot{1}$. But if α is finite, this method fails, since

$$P \upharpoonright \text{C}`P \rightarrow B`P \epsilon \alpha.$$

Thus if the total number of entities in the universe (of any one type) is finite, "$\alpha < \alpha \dotplus \dot{1}$" fails when $C``\alpha = \iota`\text{V}$, which is just the crucial case for Burali-Forti's proof. Hence as it stands, his proof is only applicable if we assume the axiom of infinity; it might, therefore, be regarded as a reductio ad absurdum of the axiom of infinity, *i.e.* as showing that the total number of entities of any one type is finite.

In order to make it plain that the paradox does not depend upon the axiom of infinity, we have above stated it in a form independent of this

axiom. The paradox, stated simply, is as follows: The ordinal number of the series of ordinals from 0_r (including 1_s) to any ordinal α is $\alpha \dot{+} \dot{1}$; hence $\alpha \dot{+} \dot{1}$ exists, and is therefore $> \alpha$. But the ordinal α is similar to the segment of the series of ordinals consisting of the predecessors of α, and is therefore less than the ordinal number of all ordinals. Hence the ordinal number of all ordinals is greater than every ordinal, and therefore than itself, which is absurd; moreover, though the greatest of all ordinals, it can be increased by the addition of $\dot{1}$, which is again absurd.

In order to dispel the above paradox, it is only necessary to make the types explicit. In the proposition

$$P \epsilon \Omega . \supset . P \text{ less } N \qquad \text{(B)},$$

upon which the paradox depends, the relation "less" is not homogeneous. N is of the same type as M, which is defined as $\text{Nr}\text{'less}$, where $C\text{'less} = \Omega$. Thus $\text{Nr}\text{'}P \epsilon C\text{'}N$. Thus N, as it occurs in (B), should really be $N \upharpoonright t\text{'}\text{N}_0\text{r}\text{'}P$, *i.e.* $N \upharpoonright t\text{'}t\text{'}P$, *i.e.* $N(P, P)$, according to the definition $*65{\cdot}12$. We have therefore

***256·53.** $\vdash : P \epsilon \Omega . \supset . P \text{ less } N \upharpoonright t\text{'}\text{N}_0\text{r}\text{'}P$

but this does not allow the inference

$$N \upharpoonright t\text{'}\text{N}_0\text{r}\text{'}P \text{ less } N \upharpoonright t\text{'}\text{N}_0\text{r}\text{'}P,$$

which is what would be required in order to elicit a paradox. The correct inference is, substituting for $N \upharpoonright t\text{'}\text{N}_0\text{r}\text{'}P$ the equivalent form $N(P, P)$,

$$N(P, P) \text{ less } N\{N(P, P), N(P, P)\}.$$ or, more generally,

***256·56.** $\vdash . (N \upharpoonright \lambda) \text{ less } \{N \upharpoonright (t\text{'}t_{00}\text{'}\lambda)\}$

Thus in higher types there are greater ordinals than any to be found in lower types. This fact is what gave rise to the paradox, as the corresponding fact in cardinals gave rise to the paradox of the greatest cardinal.

The above proposition assumes that M is homogeneous, since otherwise "$C\text{'}M$" is not significant. But M is significant even when it is not homogeneous. Thus the conditions of significance in the above proposition impose a limitation upon M which is not always imposed upon M.

$\vdash . (1) . (4) . \supset \vdash .$ Prop

When types are neglected, the above proposition appears as

$$N \text{ less } N,$$

which is impossible, and embodies Burali-Forti's paradox. In the form proved above, however, the paradox has disappeared, and we have instead the proposition that in higher types longer series are possible than in lower ones.

*257. THE TRANSFINITE ANCESTRAL RELATION.

Summary of *257.

In this number, we are concerned with an extension of the notions of R_* and R_{po}. This extension requires two relations, R and Q. It is most easily explained by first defining the "transfinite posterity" of a term x with respect to R and Q; this class is an extension of $\overleftarrow{R_*}\text{‘}x$. This class is generated as follows. Let us suppose, to aid the imagination, that Q is more or less serial in character, and that R is a many-one relation contained in Q. Then the transfinite posterity of x with respect to R and Q is generated as follows: Starting from x, we travel down the posterity of x with respect to R (*i.e.* $\overleftarrow{R_*}\text{‘}x$) as long as we can; if the whole class $\overleftarrow{R_*}\text{‘}x$ has a limit with respect to Q, we begin again with this limit, which is to be included in the transfinite posterity of x with respect to R and Q; if the limit is y, we travel down $\overleftarrow{R_*}\text{‘}y$, and include the limit of this class with respect to Q, and so on, as long as we still have either terms belonging to $\text{D}\text{‘}R$ or classes belonging to $\text{Ɑ}\text{‘}\text{lt}_Q$. The whole of the terms so obtainable constitute the transfinite posterity of x with respect to R and Q. which we will denote* by $(R*Q)\text{‘}x$.

In order to obtain a symbolic definition of this class, let us call a class σ "transfinitely hereditary" when not only $\breve{R}\text{“}\sigma \subset \sigma$, as in the ordinary hereditary class, but also if we take any existent sub-class μ of $\sigma \cap C\text{‘}Q$, if μ has a limit with respect to Q, that limit is to be a member of σ. Thus σ is to be such that the R-successor of any member of σ belongs to σ and the Q-limit of any existent sub-class of $\sigma \cap C\text{‘}Q$ belongs to σ (so long as these exist). That is, $\breve{R}\text{“}\sigma \subset \sigma$ and $\mu \subset \sigma \,.\, \exists ! \mu \cap C\text{‘}Q \,.\, \supset_\mu .\, \overrightarrow{\text{lt}_Q}\text{‘}\mu \subset \sigma$. Using the notion of the derivative of a class with respect to Q, introduced in *216, the condition $\mu \subset \sigma \,.\, \exists ! \mu \cap C\text{‘}Q \,.\, \supset_\mu .\, \overrightarrow{\text{lt}_Q}\text{‘}\mu \subset \sigma$ reduces to $\delta_Q\text{‘}\sigma \subset \sigma$, in virtue of *216·1. Hence σ is transfinitely hereditary with respect to R and Q if

$$\breve{R}\text{“}\sigma \cup \delta_Q\text{‘}\sigma \subset \sigma.$$

* This meaning for $R*Q$ has no connection with the meaning temporarily assigned to this symbol in *95.

We may now define the transfinite posterity of x with respect to R and Q as all members of $C'Q$ which belong to every transfinitely hereditary class to which x belongs, *i.e.* we put

$$(R*Q)'x = C'Q \cap \hat{y}\{x \in \sigma \,.\, \breve{R}``\sigma \cup \delta_Q`\sigma \subset \sigma \,.\, \supset_\sigma \,.\, y \in \sigma\} \quad \text{Df.}$$

Then the analogue of R_* is $\hat{x}\hat{y}\{y \in (R*Q)'x\}$. This relation, however, is less important than the analogue of R_{po} limited to the posterity of x. This analogue, assuming Q to be transitive, will be $Q \upharpoonleft (R*Q)'x$. For this we introduce the two notations Q_{Rx} and $Q(R, x)$, the latter being more convenient when either R or x is replaced by a more complicated expression. Thus we put

$$Q_{Rx} = Q(R, x) = Q \upharpoonleft (R*Q)'x \quad \text{Df.}$$

If Q is a well-ordered series and $R = Q_1$, Q_{Rx} is merely the series Q beginning with x, and $(R*Q)'x = \overleftarrow{Q_*}'x = \overleftarrow{Q}'x \cup \iota'x$ if $x \in C'Q$. Thus in this case, if $x = B'Q$, $Q_{Rx} = Q$. But the importance of Q_{Rx} is in cases where Q is not completely serial, but becomes so when limited to $(R*Q)'x$. In these cases, Q will, in applications, almost always be logical inclusion combined with diversity, or the converse of this; *i.e.* it will be either

$$\hat{\alpha}\hat{\beta}(\alpha \subset \beta \,.\, \alpha \neq \beta)$$

or

$$\hat{M}\hat{N}(M \subseteq N \,.\, M \neq N),$$

or the converse of one of these. In the case of $\hat{\alpha}\hat{\beta}(\alpha \subset \beta \,.\, \alpha \neq \beta)$, we have

$$\text{lt}_Q = s \upharpoonright (-\text{Cl}'\text{max}_Q) \,.\, \text{tl}_Q = p \upharpoonright (-\text{Cl}'\text{min}_Q),$$

as will be proved in *258.

In the present number, we are concerned in proving that, under certain circumstances, $Q_{Rx} \in \Omega$. The proof proceeds on the lines of Zermelo's second proof* of his theorem that if a selection exists from all the existent sub-classes of a given class, then the given class can be well-ordered.

Before proceeding to treat of this subject, however, it is necessary to prove some elementary properties of $(R*Q)'x$. These are given in the propositions preceding *257·2.

We have

***257·11.** $\vdash : x \in \sigma \,.\, \breve{R}``\sigma \cup \delta_Q`\sigma \subset \sigma \,.\, \supset \,.\, (R*Q)'x \subset \sigma$

Thus in order to prove that $(R*Q)'x$ is contained in a class σ, we have to prove (1) that x belongs to σ, (2) that the R-successors of members of σ are members of σ, *i.e.* that σ is hereditary with respect to R, (3) that the derivative of σ with respect to Q is contained in σ, *i.e.* that if μ is any existent sub-class of $\sigma \cap C'Q$ which has a Q-limit, this limit is a member of σ.

* "Neuer Beweis für die Möglichkeit einer Wohlordnung," *Math. Annalen*, LXV. p. 107 (1907). His first proof, which was somewhat more complicated, was published in *Math. Annalen*, LIX. p. 514 (1904).

***257·111.** $\vdash . (R*Q)`x \subset C`Q$

***257·12.** $\vdash : x \in C`Q . \equiv . x \in (R*Q)`x$

***257·123.** $\vdash : R \mathrel{\mathsf{G}} Q . \supset . \breve{R}``(R*Q)`x \subset (R*Q)`x$

I.e. if $R \mathrel{\mathsf{G}} Q, (R*Q)`x$ is hereditary with respect to $R$. The hypothesis $R \mathrel{\mathsf{G}} Q$ is required for most of the properties of $(R*Q)`x$.

***257·125.** $\vdash : R \mathrel{\mathsf{G}} Q . x \in C`Q . \supset . \overleftarrow{R_*}`x \subset (R*Q)`x$

Thus if $x \in C`Q$, the $R$-posterity of $x$ is contained in $(R*Q)`x$.

***257·13.** $\vdash : \mu \subset (R*Q)`x . \exists ! \mu . \supset . \overrightarrow{\mathrm{lt}_Q}`\mu \subset (R*Q)`x$

***257·14.** $\vdash : R \mathrel{\mathsf{G}} Q . \supset . (R*Q)`x \subset \overleftarrow{Q_*}`x$

Thus $(R*Q)`x$ is wholly contained in the Q-posterity of x.

The following propositions (*257·2—·36) are concerned in proving $Q_{Rx} \in \Omega$, with a suitable hypothesis. This hypothesis is

$$Q \in \mathrm{Rl}`J \cap \mathrm{trans} . R \in \mathrm{Rl}`Q \cap \mathrm{Cls} \to 1 . \mathrm{lt}_Q \upharpoonright \mathrm{Cl\,ex}`(R*Q)`x \in 1 \to \mathrm{Cls}.$$

We assume, to begin with, only part of this hypothesis, namely,

$$Q \in \mathrm{Rl}`J \cap \mathrm{trans} . R \in \mathrm{Rl}`Q \cap \mathrm{Cls} \to 1.$$

Thus to prove $Q_{Rx} \in \mathrm{Ser}$, we only have to prove $Q_{Rx} \in \mathrm{connex}$, *i.e.*

$$y \in (R*Q)`x . \supset . (R*Q)`x \subset \overleftrightarrow{Q}`y,$$

or, what comes to the same thing,

$$(R*Q)`x \subset p`\overleftrightarrow{Q}``(R*Q)`x.$$

Let us put $$\sigma_1 = (R*Q)`x \cap p`\overleftrightarrow{Q}``(R*Q)`x.$$

Then any member of σ_1 may be called a "connected term," because it is connected by Q or $\breve{Q}$ with every other term of $(R*Q)`x$. (A connected relation is then a relation whose field consists entirely of connected terms.) We wish to prove that $\sigma_1$ is a transfinitely hereditary class, and therefore equal to $(R*Q)`x$. We do this, not directly, but by combining σ_1 with another class σ_2 defined as follows. Consider those members z of $(R*Q)`x$ which are such that their successors in $Q_{Rx}$ consist of $\breve{R}`z$ and its successors in Q_{Rx}, *i.e.* put

$$\tau = (R*Q)`x \cap \hat{z}\{\overleftarrow{Q_{Rx}}`z = \overleftarrow{(Q_{Rx})_*}`\breve{R}`z\}.$$

It will be observed that, even when Q is transitive, Q_* and $(Q_{Rx})_*$ are still useful. In this case, $(Q_{Rx})_* = Q_{Rx} \cup I \upharpoonright C`Q_{Rx}$, so that $\overleftarrow{(Q_{Rx})_*}`\breve{R}`z$ consists of $\breve{R}`z$ and its successors in Q_{Rx}. We then consider the class σ_2 consisting of those terms y whose predecessors are all members of τ, *i.e.* we put

$$\sigma_2 = (R*Q)`x \cap \hat{y}\{zQy . z \in (R*Q)`x . \supset_z . \overleftarrow{Q_{Rx}}`z = \overleftarrow{(Q_{Rx})_*}`\breve{R}`z\}.$$

Finally we put $\sigma = \sigma_1 \cap \sigma_2$, *i.e.*

$$\sigma = (R*Q)`x \cap p`\overleftrightarrow{Q}``(R*Q)`x \cap \hat{y}\{zQy . z \in (R*Q)`x . \supset_z . \overleftarrow{Q_{Rx}}`z = \overleftarrow{(Q_{Rx})_*}`\breve{R}`z\}.$$

The reason for this process is that it is easier to prove that σ is a transfinitely hereditary class than it is to prove this directly for σ_1; and the result follows immediately for σ_1 when it has been proved for σ.

We have then to prove $\breve{R}\text{‘‘}\sigma \subset \sigma \,.\, \delta_Q\text{‘}\sigma \subset \sigma$.

The first step is to prove

$$y \in \sigma \,.\, \supset \,.\, \overleftarrow{Q_{Rx}}\text{‘}y = \overleftarrow{Q_{Rx}}\text{‘}\breve{R}\text{‘}y \cup \iota\text{‘}\breve{R}\text{‘}y.$$

This is proved by transfinite induction, by showing that

$$\overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$$

is a transfinitely hereditary class, whence the result, because, by hypothesis,

$$(R*Q)\text{‘}x = \overrightarrow{(Q_{Rx})_*}\text{‘}y \cup \overleftarrow{Q_{Rx}}\text{‘}y.$$

The proof that $\overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$ is a transfinitely hereditary class is as follows.

If $z \in \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$, $\breve{R}\text{‘}z \in \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$. If $z = y$, $\breve{R}\text{‘}z = \breve{R}\text{‘}y$.

If $z \in \overrightarrow{Q_{Rx}}\text{‘}y$, then since by the hypothesis $\overleftarrow{Q_{Rx}}\text{‘}z = \overleftarrow{(Q_{Rx})_*}\text{‘}\breve{R}\text{‘}z$, we have

$$y \in \overleftarrow{(Q_{Rx})_*}\text{‘}\breve{R}\text{‘}z, \text{ i.e. } \breve{R}\text{‘}z \in \overrightarrow{Q_*}\text{‘}y.$$

Hence $z \in (R*Q)\text{‘}x \cap (\overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y) \,.\, \supset \,.\, \breve{R}\text{‘}z \in \overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$.

We have next to prove

$$\mu \subset (R*Q)\text{‘}x \cap (\overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y) \,.\, \exists ! \mu \,.\, \supset \,.\, \overrightarrow{\mathrm{lt}_Q}\text{‘}\mu \subset \overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y.$$

If $\exists ! \mu \cap \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$, then $\overrightarrow{\mathrm{lt}_Q}\text{‘}\mu \subset \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$.

If $\mu \subset \overrightarrow{Q_*}\text{‘}y \,.\, y \in \mu$, then $y \in \overrightarrow{\max_Q}\text{‘}\mu$, and $\overrightarrow{\mathrm{lt}_Q}\text{‘}\mu = \Lambda$.

If $\mu \subset \overrightarrow{Q}\text{‘}y$, we have $y \in p\text{‘}\overleftarrow{Q}\text{‘‘}\mu$, whence $w \,\mathrm{lt}_Q \mu \,.\, \supset \,.\, \sim(yQw)$, whence, since y, by hypothesis, is a connected term, wQ_*y.

Hence in any case $\overrightarrow{\mathrm{lt}_Q}\text{‘}\mu \subset \overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$. Hence $\overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y$ is hereditary, and therefore contains $(R*Q)\text{‘}x$; and hence

$$\overleftarrow{Q_{Rx}}\text{‘}y = \overleftarrow{(Q_{Rx})_*}\text{‘}\breve{R}\text{‘}y \,.\, \overrightarrow{(Q_{Rx})_*}\text{‘}y = \overrightarrow{Q_{Rx}}\text{‘}\breve{R}\text{‘}y.$$

This shows that $\breve{R}\text{‘}y$ is a member of σ_2. For by hypothesis this holds of all predecessors of y, and we have now shown (1) that it also holds of y, (2) that y is the only predecessor of $\breve{R}\text{‘}y$ which does not precede y. This is the first step towards proving that σ is transfinitely hereditary.

It follows immediately, from what has now been proved, that if $y \in \sigma$, $\breve{R}\text{‘}y$ (if it exists) is a connected term. For by hypothesis

$$(R*Q)\text{‘}x \subset \overrightarrow{Q_*}\text{‘}y \cup \overleftarrow{Q}\text{‘}y,$$

whence, by what we have just proved,

$$(R*Q)\text{‘}x \subset \overrightarrow{Q}\text{‘}\breve{R}\text{‘}y \cup \overleftarrow{Q_*}\text{‘}\breve{R}\text{‘}y,$$

whence $\breve{R}`y$ is a connected term. Hence $\breve{R}`y \in \sigma$. Hence $\breve{R}``\sigma \subset \sigma$.

It remains to prove $\qquad \delta_Q`\sigma \subset \sigma.$

Just as $\breve{R}``\sigma \subset \sigma$ was proved by proving $\overleftarrow{Q}`y = \overleftarrow{Q_*}`\breve{R}`y$, so $\delta_Q`\sigma \subset \sigma$ is proved by proving

$$p`\overleftarrow{Q}``\mu \subset \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu,$$

provided $\qquad \mu \subset \sigma \,.\, \exists\,!\,\mu \,.\, \sim\exists\,!\,\overrightarrow{\mathrm{max}_Q}`\mu\,;$

and this is proved by showing that $Q``\mu \cup \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu$ is a transfinitely hereditary class.

To show that $Q``\mu \cup \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu$ is a transfinitely hereditary class if

$$\mu \subset \sigma \,.\, \exists\,!\,\mu \,.\, \sim\exists\,!\,\overrightarrow{\mathrm{max}_Q}`\mu,$$

we observe that by hypothesis

$$z \in Q_{Rx}``\mu \,.\, \supset .\, \overleftarrow{Q_{Rx}}`z = \overleftarrow{(Q_{Rx})_*}`\breve{R}`z \,.\, \supset .\, \exists\,!\,\mu \cap \overleftarrow{(Q_{Rx})_*}`\breve{R}`z.$$

Hence $\breve{R}`z \in (Q_{Rx})_*``\mu$; and hence, since by hypothesis $\mu \subset Q``\mu$,

$$\breve{R}`z \in Q_{Rx}``\mu.$$

Hence $\qquad \breve{R}``\{(Q*R)`x \cap Q``\mu\} \subset (Q*R)`x \cap Q``\mu.$

Also obviously $\qquad \breve{R}``\breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu \subset \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu.$

Hence putting $\qquad \rho = (Q*R)`x \cap (Q``\mu \cup \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu),$

we have $\qquad \breve{R}``\rho \subset \rho.$

We have now to prove $\qquad \delta_Q`\rho \subset \rho,$

i.e. $\qquad \alpha \subset \rho \,.\, \exists\,!\,\alpha \,.\, \sim\exists\,!\,\overrightarrow{\mathrm{max}_Q}`\alpha \,.\, \supset .\, \overrightarrow{\mathrm{lt}_Q}`\alpha \subset \rho.$

If $\alpha \subset Q``\mu$, it is obvious (since $\mu$ is composed entirely of connected terms) that $\overrightarrow{\mathrm{seq}_Q}`\alpha \subset Q``\mu \cup \overrightarrow{\mathrm{lt}_Q}`\mu$.

On the other hand, if $\exists\,!\,\alpha \cap \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu$, then $\alpha \cap Q``\mu$, if it exists, does not affect the value of the limit of α, which is the limit of $\alpha \cap \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu$, which is obviously contained in $\breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu$. Hence $\delta_Q`\mu \subset \mu$. Hence μ is transfinitely hereditary, and we have

$$\mu \subset \sigma \,.\, \exists\,!\,\mu \,.\, \sim\exists\,!\,\overrightarrow{\mathrm{max}_Q}`\mu \,.\, \supset .\, (R*Q)`x \subset Q``\mu \cup \breve{Q}_*``\overrightarrow{\mathrm{lt}_Q}`\mu.$$

At this point it is necessary to assume

$$\mathrm{lt}_Q \upharpoonright \mathrm{Cl\,ex}`(R*Q)`x \in 1 \rightarrow \mathrm{Cls}.$$

This being assumed, we have, by what has just been proved,

$$\mu \subset \sigma \,.\, \exists\,!\,\mu \,.\, \exists\,!\,\overrightarrow{\mathrm{lt}_Q}`\mu \,.\, \supset .\, (R*Q)`x \subset Q``\mu \cup \overleftarrow{Q_*}`\mathrm{lt}_Q`\mu \,.$$
$$\supset .\, (R*Q)`x \subset \overrightarrow{Q}`\mathrm{lt}_Q`\mu \cup \overleftarrow{Q_*}`\mathrm{lt}_Q`\mu.$$

Hence $\mathrm{lt}_Q‘\mu$ is a connected term. Hence

$$\delta_Q‘\sigma \subset p‘\overleftrightarrow{Q}“(R*Q)‘x.$$

We only require further

$$\mu \subset \sigma \,.\, \exists\,!\,\mu \,.\, \exists\,!\,\overrightarrow{\mathrm{lt}_Q}‘\mu \,.\supset: zQ\,\mathrm{lt}_Q‘\mu \,.\, z \in (R*Q)‘x \,.\supset_z.\, \overleftarrow{Q_{Rx}}‘z = \overleftarrow{(Q_{Rx})_*}‘\breve{R}‘z.$$

Now by what we have just proved, $zQ\,\mathrm{lt}_Q‘\mu \,.\equiv.\, z \in Q“\mu$; and by the definition of σ, since $\mu \subset \sigma$, we have

$$z \in Q“\mu \,.\supset.\, \overleftarrow{Q_{Rx}}‘z = \overleftarrow{(Q_{Rx})_*}‘\breve{R}‘z.$$

Hence we arrive at $\delta_Q‘\sigma \subset \sigma$. Since we have already proved $\breve{R}“\sigma \subset \sigma$, it follows that σ is hereditary, and $(R*Q)‘x \subset \sigma$, *i.e.*

$$y \in (R*Q)‘x \,:\supset_y: y \in p‘\overleftrightarrow{Q}“(R*Q)‘x : zQ_{Rx}y \,.\supset_z.\, \overleftarrow{Q_{Rx}}‘z = \overleftarrow{(Q_{Rx})_*}‘\breve{R}‘z,$$

i.e. $\qquad Q_{Rx} \in \mathrm{connex} : z \in \mathrm{D}‘Q_{Rx} \,.\supset_z.\, \overleftarrow{Q_{Rx}}‘z = \overleftarrow{(Q_{Rx})_*}‘\breve{R}‘z.$

Hence $Q_{Rx} \in \mathrm{Ser}$. Hence also the immediate successor of every term z in $\mathrm{D}‘Q_{Rx}$ is $\breve{R}‘z$, so that

$$\mathrm{D}‘Q_{Rx} \subset \mathrm{D}‘R \,.\, (Q_{Rx})_1 = R \upharpoonleft (R*Q)‘x.$$

To show that $Q_{Rx} \in \Omega$, we observe that every class contained in $\mathrm{D}‘Q_{Rx}$ has a sequent, namely

$$\mathrm{seq}\,(Q_{Rx})‘\Lambda = x,$$

$$\alpha \subset \mathrm{D}‘Q_{Rx} \,.\, \exists\,!\,\overrightarrow{\max_Q}‘\alpha \,.\supset.\, \mathrm{seq}\,(Q_{Rx})‘\alpha = \breve{R}‘\max_Q‘\alpha,$$

$$\alpha \subset \mathrm{D}‘Q_{Rx} \,.\, \exists\,!\,\alpha \,.\, \sim\exists\,!\,\overrightarrow{\max_Q}‘\alpha \,.\supset.\, \mathrm{seq}\,(Q_{Rx})‘\alpha = \mathrm{lt}_Q‘\alpha,$$

whence $\qquad \alpha \subset \mathrm{D}‘Q_{Rx} \,.\supset_\alpha.\, \mathrm{E}\,!\,\mathrm{seq}\,(Q_{Rx})‘\alpha,$

which shows that $Q_{Rx} \in \Omega$.

The first derivative of Q_{Rx} is $\delta_Q‘(Q*R)‘x$, and its last term, if any, is

$$\breve{\iota}‘\{(Q*R)‘x - \mathrm{D}‘R\}, \text{ i.e. } \mathrm{lt}_Q‘\{(Q*R)‘x \cap \mathrm{D}‘R\}.$$

The hypothesis required for $Q_{Rx} \in \Omega$ is the same as for $Q_{Rx} \in \mathrm{Ser}$, namely,

$$Q \in \mathrm{Rl}‘J \cap \mathrm{trans} \,.\, R \in \mathrm{Rl}‘Q \cap \mathrm{Cls} \to 1 \,.\, \mathrm{lt}_Q \upharpoonright \mathrm{Cl\,ex}‘(R*Q)‘x \in 1 \to \mathrm{Cls}.$$

In order that Q_{Rx} may not be null, we require further $x \in \mathrm{D}‘R$.

The next set of propositions (*257·5—·56) are designed to prove that, subject to the above hypothesis together with $x \in \mathrm{D}‘R$, Q_{Rx} is the only value of P fulfilling the following conditions:

(1) P is transitive.

(2) $C‘P$ is contained in $(R*Q)‘x$.

(3) If z is any member of $\mathrm{D}‘P$, $\breve{R}‘z$ is its immediate successor.

(4) If α is any existent class contained in $C‘P$ and having no maximum, $\mathrm{lt}_Q‘\alpha$ is its P-limit.

This proposition is essential for what may be called "transfinite inductive definitions," *i.e.* definitions of a series by defining the successor of every term, and the successor of every class having no maximum.

The following illustration may make this clear. Suppose R is a many-one relation of classes to individuals; suppose we start with some class α, and proceed to $\alpha \cup \iota'\breve{R}'\alpha$, $\alpha \cup \iota'\breve{R}'\alpha \cup \iota'\breve{R}'(\alpha \cup \iota'\breve{R}'\alpha)$, and so on. At the end of this series we put its sum, *i.e.* its limit with respect to the relation $(\subset \dot{\cap} J)$; let the sum be β. We then proceed with $\beta \cup \iota'\breve{R}'\beta$, and so on, as long as possible. The series ends with a sum which is not a member of $\mathrm{D}'R$, if there is such a sum. It is evident that the series is uniquely determined by the above method of generation; the above-mentioned propositions give symbolic expression to the process expressed in words by "and so on, as long as possible."

We now begin the proof (completed in *257·34) that under certain circumstances $Q_{Rx} \in \Omega$. We first prove that the class σ introduced in *257·2 is transfinitely hereditary, and this requires as a preliminary the proof that if $y \in \sigma$, the class $\overrightarrow{(Q_{Rx})_*}\text{‘}y \cup \overleftarrow{(Q_{Rx})_*}\text{‘}\breve{R}\text{‘}y$ is transfinitely hereditary. This preliminary is provided by *257·2·21. The hypothesis of *257·2 is not all used in *257·2, but is introduced because it is required in the set of propositions of which this is the first.

This proves that the conditions in the hypothesis of $*257\cdot5$ are sufficient to determine P.

Summary of *258.

In this number, we shall first show the applicability of the propositions of *257 to the case where the Q of that number is replaced by logical inclusion combined with diversity, *i.e.* by any one of the four relations:

$$\hat{\alpha}\hat{\beta}(\alpha \subset \beta \,.\, \alpha \neq \beta), \quad \hat{\alpha}\hat{\beta}(\beta \subset \alpha \,.\, \alpha \neq \beta),$$

$$\hat{M}\hat{N}(M \Subset N \,.\, M \neq N), \quad \hat{M}\hat{N}(N \Subset M \,.\, M \neq N).$$

If we put $\qquad Q = \hat{\alpha}\hat{\beta}(\alpha \subset \beta \,.\, \alpha \neq \beta),$

and if κ is any class of classes, then $s`\kappa$ is the maximum of $\kappa$ with respect to $Q$ if $s`\kappa \in \kappa$, and the sequent of κ with respect to Q if $s`\kappa \sim\in \kappa$ (*258·1·11); similarly $p`\kappa$ is the minimum of κ if $p`\kappa \in \kappa$ and the precedent of $\kappa$ if $p`\kappa \sim\in \kappa$ (*258·101·111). Hence every class of classes has a unique maximum or a unique sequent with respect to Q, and every class of classes has a unique minimum or a unique precedent (*258·12); we have, moreover,

$$\text{lt}_Q = s \upharpoonright (-\text{Ꭰ}`\text{max}_Q) \,.\, \text{tl}_Q = p \upharpoonright (-\text{Ꭰ}`\text{min}_Q) \quad (*258{\cdot}13{\cdot}131).$$

Hence $\text{lt}_Q, \text{tl}_Q \in 1 \to \text{Cls}$ (*258·14), and Q and $\breve{Q}$ therefore satisfy the most exacting part of the hypothesis of *257·27. Also Q and $\breve{Q}$ are Dedekindian relations (*258·14). (They are not series, because they are not connected.)

An exactly similar argument applies to $\hat{M}\hat{N}(M \Subset N \,.\, M \neq N)$. Hence if Q is any one of the above four relations, and if R is a many-one contained in Q, it follows from *257·34 that Q with its field limited to the transfinite posterity of any term is a well-ordered series. If we take $Q = \hat{\alpha}\hat{\beta}(\alpha \subset \beta \,.\, \alpha \neq \beta)$, and take any initial term α, our series proceeds to continually larger classes, proceeding to the limit by taking the logical sum, *i.e.* if κ is any existent sub-class of the posterity of α, $s`\kappa = \text{limax}_Q`\kappa = \text{limax}\,(Q_{R\alpha})`\kappa$ (*258·21·22), where $Q_{R\alpha}$ has the meaning defined in *257. This process stops with $s`\{\text{D}`R \cap (R_*Q)`x\}$ if $\text{D}`R \cap (R_*Q)`x$ has no maximum; otherwise, it stops with the R-successor of this maximum, which is $\text{max}_Q`\{C`R \cap (R_*Q)`x\}$. If, on the other hand, we take $Q$ to be the converse of the above, we proceed to continually smaller classes, and the limit of any set of classes $\kappa$ having no last term is $p`\kappa$. In this case, if, starting from α, every existent sub-class of α belongs to $\text{D}`R$, the process of diminution cannot stop short of Λ. This is

the process applied in Zermelo's theorem. We have the e a class μ, assumed to be not a unit class, and a selective relation S for existent sub-classes of μ, *i.e.* a relation S for which $S \epsilon \epsilon_\Delta$'Cl ex'$\mu$. Then our relation R is the relation of α to $\alpha - \iota$'S'α, *i.e.* the relation of an existent sub-class of μ to the class resulting from taking away its S-representative. Thus $Q_{R\mu}$ is a well-ordered series, which starts from μ and ends with Λ. Omitting the final Λ, S selects a representative from every member of the field of $Q_{R\mu}$, and the series of these representatives. *i.e.* $S;Q_{R\mu}$, is similar to $Q_{R\mu}$ with the final Λ omitted. Moreover every member of μ occurs among these representatives, for, if x be any member of μ, let κ be the class of those members of C'$Q_{R\mu}$ of which x is a member. (There are such classes, because $\mu \epsilon C$'Q_{Rx} and $x \epsilon \mu$.) Then $x \epsilon p$'κ, and by what was said earlier, p'κ is a member of C'$Q_{R\mu}$. Hence, by the definition of κ, p'$\kappa \epsilon \kappa$, and therefore p'$\kappa = \max_Q$'κ. But no class smaller than p'κ can belong to κ, and therefore p'$\kappa - \iota$'S'p'κ is not a member of κ, and therefore x is not a member of p'$\kappa - \iota$'S'p'κ. Hence $x = S$'p'κ, and therefore x occurs among the representatives of members of C'$Q_{R\mu}$, which was to be proved. (The above is an abbreviated rendering of the symbolic proof given below in ∗258·301.) Hence the field of $S;Q_{R\mu}$ is μ, and therefore there is a well-ordered series having μ for its field, provided ϵ_Δ'Cl ex'μ is not null (∗258·32). This is Zermelo's theorem.

The converse of Zermelo's theorem has been already proved (∗250·51). Hence the assumption that a selection can be made from all the existent sub-classes of μ is equivalent to the assumption that μ can be well-ordered or is a unit class, *i.e.*

∗258·36. $\vdash : \mu \epsilon C``\Omega \cup 1 . \equiv . \exists ! \epsilon_\Delta$'Cl ex'$\mu$

Hence also, by ∗88·33, the multiplicative axiom is equivalent to the assumption that all classes except unit classes can be well-ordered, *i.e.*

∗258·37. $\vdash :$ Mult ax $. \equiv . C``\Omega \cup 1 =$ Cls

*259. INDUCTIVELY DEFINED CORRELATIONS.

Summary of *259.

In the theory of well-ordered relations, we often have occasion to define a relation (which is generally of the nature of a correlation) by the following process: Given a relation S, let $W\text{‘}S$ be a relation (generally a couple) which is a function of S. Let us put

$$\breve{A}_W\text{‘}S = S \cup W\text{‘}S.$$

Then, starting from $\dot\Lambda$, we form the series

$$\dot\Lambda,\ \breve{A}_W\text{‘}\dot\Lambda,\ \breve{A}_W\text{‘}\breve{A}_W\text{‘}\dot\Lambda,\ \text{etc.},$$

each of which contains all its predecessors. We proceed to the limit by taking the sum of all these relations, *i.e.* $\dot{s}\text{‘}\overleftarrow{(A_W)}_*\text{‘}\dot\Lambda$; we then proceed to $\breve{A}_W\text{‘}\dot{s}\text{‘}\overleftarrow{(A_W)}_*\text{‘}\dot\Lambda$, and so on, as long as possible. The sum of all the relations so obtained is a function of W, and is often important.

As an example, we may consider the correlation of two well-ordered series P, Q, which is dealt with in *259·2—·25 below. In this case, we put

$$W = \hat{X}\hat{T}\{X = \mathrm{seq}_P\text{‘}\mathrm{D}\text{‘}T \downarrow \mathrm{seq}_Q\text{‘}\text{Ɑ}\text{‘}T\}.$$

Hence $$W\text{‘}\dot\Lambda = \breve{A}_W\text{‘}\dot\Lambda = B\text{‘}P \downarrow B\text{‘}Q = 1_P \downarrow 1_Q,$$

$$\breve{A}_W\text{‘}\breve{A}_W\text{‘}\dot\Lambda = 1_P \downarrow 1_Q \cup 2_P \downarrow 2_Q,$$

and so on.

Proceeding in this fashion, we can continue until one at least of the two series P, Q is exhausted. We thus obtain a new proof that, of any two well-ordered series, one must be similar to a section of the other.

For convenience of notation, let us put temporarily

$$A = \hat{S}\hat{T}(S \Subset T \,.\, S \neq T) \quad \text{Dft.}$$

We then have $A \in \mathrm{Rl}\text{‘}J \cap \mathrm{trans} \,.\, A_W \in \mathrm{Rl}\text{‘}A \cap \mathrm{Cls} \to 1$, which is part of the hypothesis of *257·27 and following propositions. The rest of this hypothesis follows by analogy from *258·14 We now put

$$W_A = \dot{s}\text{‘}(A_W * A)\text{‘}\dot\Lambda \quad \text{Df.}$$

Then W_A correlates the whole of P with part or the whole of Q, or vice versa. This is proved in *259·25, below.

For other values of W, we get other results, often of a useful kind; for example we shall have occasion to use the methods of this number in $*273$, which deals with series similar to the series of rationals.

The present number gives, first, some elementary properties of $(A_W * A)`\dot{\Lambda}$ and $W_A$ for a general relation $W$, concerning which we only assume that $W`S$ is never contained in S, *i.e.* $W \dot{\cap} (\subseteq) = \dot{\Lambda}$ (except in $*259{\cdot}121{\cdot}13$, where we also assume $W \in 1 \to \mathrm{Cls}$). We then proceed to deal specially with the case where

$$W = \hat{X}\hat{T}\{X = \mathrm{seq}_P`\mathrm{D}`T \downarrow \mathrm{seq}_Q`\mathrm{G}`T\}$$

as explained above.

$*259{\cdot}01.\quad A = \hat{S}\hat{T}(S \subseteq T \,.\, S \neq T) \quad$ Dft [$*259$]

$*259{\cdot}02.\quad A_W = \hat{S}\hat{T}(T = S \cup W`S) \quad$ Dft [$*259$]

$*259{\cdot}03.\quad W_A = \dot{s}`(A_W * A)`\dot{\Lambda} \quad$ Df

In the following propositions, which result from those of $*258$, it is essential to have $A_W \subseteq A$. For this we require that $W`S$, when it exists, shall not be contained in S. It will be observed that, according to the above definition,

$$A_* = \hat{S}\hat{T}(S \subseteq T).$$

Hence instead of using "$\subseteq$" as a relation, which is notationally awkward, we shall use A_*. Thus the condition we wish to impose upon W is that we are never to have $(W`S)A_*S$. This is insured by

$$W \dot{\cap} A_* = \dot{\Lambda},$$

which accordingly appears as hypothesis in the following propositions.

$*259{\cdot}1.\quad \vdash : A \in \mathrm{Rl}`J \cap \mathrm{trans} \,.\, \mathrm{lt}_A \in 1 \to \mathrm{Cls} :$
$$W \dot{\cap} A_* = \dot{\Lambda} \,.\supset .\, A_W \in \mathrm{Rl}`A \cap \mathrm{Cls} \to 1 \,.\, A\,(A_W, \dot{\Lambda}) \in \Omega$$

Dem.

The above affords a new proof of *254·37, which asserts that if P and Q are well-ordered series, one must be similar to a section of the other. In virtue of *259·25 (which has been proved without using the propositions of *254), W_A is the correlator which correlates the whole of one series with part or the whole of the other.

It will be observed that the relations $(A_W * A)`\dot{\Lambda}$ are the class of correlators of sections of $P$ with sections of $Q$, provided $P, Q \in \Omega - \iota`\dot{\Lambda}$; *i.e.*

$\vdash : \text{Hp} *259\cdot2 . P, Q \in \Omega - \iota`\dot{\Lambda} . \supset .$

$$(A_W * A)`\dot{\Lambda} = \hat{T}\{(\exists M, N) . M \in C`P_\varsigma . N \in C`Q_\varsigma . T \in M \,\overline{\text{smor}}\, N\}.$$

SECTION E.

FINITE AND INFINITE SERIES AND ORDINALS.

Summary of Section E.

In the present section we shall be concerned first with the distinction of finite and infinite as applied to series and ordinals. We shall then establish the distinguishing properties of finite ordinals, and shall deal with the smallest of infinite ordinals, namely ω, the ordinal number of a *progression*. Finally we shall briefly consider certain special ordinals, and the series of cardinals applicable to well-ordered infinite series, namely the series of "Alephs," as they are called after Cantor's usage.

In dealing with the finite and the infinite as applied to series, we have constant need of the relation $(P_1)_{\text{po}}$, where P is the generating relation of the series. We have

$$x (P_1)_{\text{po}}\, y \,.\equiv.\, P(x \mapsto y) \,\epsilon\, \text{Cls induct} - \iota\text{`}\Lambda,$$

i.e. "$x (P_1)_{\text{po}}\, y$" holds when, and only when, there is a finite number of intermediaries between x and y. When P is finite, we have

$$P = (P_1)_{\text{po}},$$

but we may have this when P is not finite. The infinite series for which this holds are progressions and their converses (which we will call regressions), and series consisting of a regression followed by a progression, of which an instance is afforded by the negative and positive finite integers in order of magnitude.

*260. ON FINITE INTERVALS IN A SERIES.

Summary of *260.

In the present number we are concerned with the relation which holds between x and y when the interval $P(x \vdash y)$ is an inductive class other than Λ, or when the interval $P(x \vdash\!\dashv y)$ is an inductive class of at least two terms. This relation holds if x and y have any relation of the class $\text{fin}`P$ (defined in *121). We will call this relation P_{fn}. Thus we put

$$P_{\text{fn}} = \dot{s}`\text{fin}`P \quad \text{Df.}$$

Then $xP_{\text{fn}}y$ holds when $xP_\nu y$, where ν is an inductive cardinal other than 0 (*260·1). This relation will take us from x to any later term which can be reached without passing to the limit. But if in the interval $P(x \dashv y)$ there is any term which has no immediate predecessor, *i.e.* any member of $C`P - \text{Cl}`P_1$, then we shall not have $xP_{\text{fn}}y$. Thus P_{fn} confines us to terms which are at a finite distance from our starting-point. We shall find that if $P \in \Omega$, a necessary condition for the finitude of P is $P = P_{\text{fn}}$. This is not a *sufficient* condition, since it does not exclude progressions, but these are the only infinite series it admits, and these are excluded by the assumption $\text{E}\,!\,B`\breve{P}$.

Although P_{fn} is not in general serial when P or P_{po} is serial, it becomes serial when confined to the posterity or the ancestry or the family of any term with respect to itself (*260·32·4). When a series P is well-ordered, the whole series can be divided into constituent series, each of which is the family of any one of its members with respect to P_{fn} (except when P has a last term which has no immediate predecessor, in which case this last term must be omitted). (Cf. *264.) Each of these series (except the last, possibly) is a progression, and the last is either finite or a progression. Hence every infinite well-ordered series consists of a series of progressions followed by a finite tail (which may be null); hence the cardinal of the field of an infinite well-ordered series is a multiple of $\aleph_0$. These results will be proved later; for the present we are concerned with the proof that the family of any term with respect to P_{fn} is a series of which the generating relation is P_{fn} with its field confined to that family.

In the present number we are chiefly concerned with the relations of P_{fn} to P_1. We have

***260·27.** $\vdash : P_{\text{po}} \in \text{Ser} \,.\supset .\, P_{\text{fn}} = (P_1)_{\text{po}}$

This proposition will be used very frequently throughout this section.

Without any hypothesis we have

***260·12.** $\vdash .\, P_{\text{fn}} \subset P_{\text{po}}$

We have also

***260·15.** $\vdash .\, P_{\text{fn}} = (P_{\text{po}})_{\text{fn}}$

Hence whatever properties of P_{fn} result from the hypothesis that P is a series will result from the weaker hypothesis that P_{po} is a series.

If P_{po} is a series, P_{fn} is contained in diversity and is transitive (*260·202), but not in general connected.

In comparing P_{fn} and $(P_1)_{\text{po}}$, we constantly need the proposition

***260·22.** $\vdash : P_{\text{po}} \in \text{Ser} \,.\supset .\, (P_1)_1 = P_1 \,.\, P_1 \in 1 \to 1 \,.\, (P_1)_{\text{po}} \subset J$

From *260·3 to the end of the number, we are concerned with the result of limiting the field of P_{fn} to the ancestry, posterity or family of some member of its field. We have

***260·33.** $\vdash : P_{\text{po}} \in \text{Ser} \,.\, x \in \text{D}`P_1 \,.\, P_1 = R \,.\supset .$
$$P_{\text{fn}} \upharpoonleft (\iota`x \cup \overleftarrow{P_{\text{fn}}}`x) = (\overleftarrow{R_*}`x) \rceil R_{\text{po}} = \{(\overleftarrow{R_*}`x) \rceil R\}_{\text{po}} = \{R \upharpoonright (\overleftarrow{R_{\text{po}}}`x)\}_{\text{po}}$$

***260·34.** $\vdash : \text{Hp} \,\text{*}260·33 \,.\supset .\, \{P_{\text{fn}} \upharpoonleft (\iota`x \cup \overleftarrow{P_{\text{fn}}}`x)\}_1 = (\overleftarrow{R_*}`x) \rceil R = R \upharpoonright \overleftarrow{R_{\text{po}}}`x$

$\vdash . (2) . (3) . (4) . \supset \vdash . \text{Prop}$

The following propositions are concerned in proving that if $P_{\text{po}} \epsilon \text{Ser}$, $P_{\text{fn}} = (P_1)_{\text{po}}$ and $P_\nu = (P_1)_\nu$. Note that "$x (P_1)_{\text{po}} y$" means that we can get from x to y by a finite number of steps from one term to the next, so that the series contains no limit-points between x and y. The relation "$x (P_1)_\nu y$" means that $\nu -_c 1$ intermediate terms

$$z_1, z_2, z_3, \ldots z_{\nu -_c 1}$$

can be found, each of which has the relation P_1 to its neighbour, and such that $x P_1 z_1$ and $z_{\nu -_c 1} P_1 y$. Thus we have to prove that, provided P_{po} is a series, this occurs when, and only when, the number of terms in the interval $P(x \mapsto y)$ is $\nu +_c 1$.

***260·2.** $\vdash : P_{\text{po}} \epsilon \text{connex} . x P_* y . y P_* z . \supset . P(x \mapsto z) = P(x \mapsto y) \cup P(y \mapsto z)$

We shall not have in general $P_{\text{po}} \epsilon \text{Ser} . \supset . P_{\text{fn}} \epsilon \text{Ser}$, because P_{fn} is in general not connected. P_{fn} only relates two terms which are at a finite distance from each other, and hence divides P_{po} into a number of mutually exclusive parts. We shall only have $P_{\text{fn}} \epsilon \text{Ser}$ when every interval in the series is finite.

In the above proposition, "Induct" refers to ∗120·13. The "$\phi\xi$" of ∗120·13 is replaced by

$$xR_\xi y \,.\, \supset_y \,.\, P(x \vdash\!\dashv y) = R(x \vdash\!\dashv y).$$

Thus (2), in the above proof, is (when ν is replaced by ξ)

$$\xi \epsilon \text{NC induct} . \phi\xi . \supset . \phi(\xi +_c 1),$$

and (3) is $\phi 0$.

Hence, by $*120{\cdot}13$, we have

$$\alpha \epsilon \text{NC induct} . \supset . \phi\alpha,$$

i.e. $\nu \epsilon \text{NC induct} . \supset : xR_\nu y . \supset_y . R(x \mapsto y),$

which is the inference drawn in the above proof.

Wherever "Induct" is given as a reference, it indicates a process such as the above, making use of $*120{\cdot}13$ or $*120{\cdot}11$.

Observe that the two series $P_{fn} \sqsubset \overleftrightarrow{P}_{fn}'x$ and $P_{fn} \sqsubset \overleftrightarrow{P}_{fn}'y$ are either identical or have no common terms in their fields. This results immediately from *97·16, since the fields of the two series are $(\overleftrightarrow{P}_1)_*'x$ and $(\overleftrightarrow{P}_1)_*'y$.

*261. FINITE AND INFINITE SERIES.

Summary of *261.

In this number we define finite and infinite series, and we show that, where well-ordered series are concerned, there is only one kind of finitude, *i.e.* there is not the distinction, which exists in cardinals, between "inductive" and "non-reflexive." We also give various equivalent forms of the distinction between finite and infinite series, and some of the simpler properties of each. The propositions of this number are numerous and important.

We define an infinite series as one whose field is a reflexive class, and a finite series as one which is not infinite. Thus we put

$$\text{Ser infin} = \text{Ser} \cap \breve{C}``\text{Cls refl} \quad \text{Df},$$

$$\Omega \text{ infin} = \Omega \cap \breve{C}``\text{Cls refl} \quad \text{Df},$$

$$\text{Ser fin} = \text{Ser} - \text{Ser infin} \quad \text{Df},$$

$$\Omega \text{ fin} = \Omega - \Omega \text{ infin} \quad \text{Df}.$$

We also put, to begin with,

$$\Omega \text{ induct} = \Omega \cap \breve{C}``\text{Cls induct} \quad \text{Df},$$

but in the course of this number we prove

***261·42.** $\vdash . \Omega \text{ fin} = \Omega \text{ induct}$

so that the symbol "Ω induct" is not required after the present number.

After some preliminary propositions, we proceed (*261·2 ff.) to various criteria of finitude and infinity. We have

***261·25.** $\vdash :. P \in \text{Ser} . \supset :$

$$C`P \in \text{Cls induct} - \iota`\Lambda . \equiv . P = P_{\text{fn}} . \text{E} ! B`P . \text{E} ! B`\breve{P}$$

The condition $P = P_{\text{fn}}$ insures that every interval is finite, but this still leaves it possible for our series to be a progression, or its converse, or the converse of a progression followed by a progression (*i.e.* the type of the negative and positive finite integers in order of magnitude). The third of these

possibilities is excluded by either $\mathrm{E}\,!\,B\text{'}P$ or $\mathrm{E}\,!\,B\text{'}\breve{P}$; the second is excluded by $\mathrm{E}\,!\,B\text{'}P$, and the first by $\mathrm{E}\,!\,B\text{'}\breve{P}$. We have

***261·212.** $\vdash :. P \in \Omega . \supset : \text{Cl}\text{'}P_1 = \text{Cl}\text{'}P . \equiv . P = (P_1)_{\text{po}} . \equiv . P = P_{\text{fn}}$

"$\text{Cl}\text{'}P_1 = \text{Cl}\text{'}P$" means that every term except the first has an immediate predecessor. We have

***261·26.** $\vdash : P \in \text{Ser} . \alpha \subset C\text{'}P . \exists ! \alpha . \alpha \in \text{Cls induct} . \supset . \mathrm{E}\,!\,\text{min}_P\text{'}\alpha . \mathrm{E}\,!\,\text{max}_P\text{'}\alpha$

and

***261·27.** $\vdash :. P \in \text{Ser} : \alpha \subset C\text{'}P . \exists ! \alpha . \supset_\alpha . \mathrm{E}\,!\,\text{min}_P\text{'}\alpha . \mathrm{E}\,!\,\text{max}_P\text{'}\alpha : \supset .$
$P = P_{\text{fn}} . C\text{'}P \in \text{Cls induct}$

whence we obtain

***261·28.** $\vdash :: P \in \text{Ser} . \supset :.$
$\alpha \subset C\text{'}P . \exists ! \alpha . \supset_\alpha . \mathrm{E}\,!\,\text{min}_P\text{'}\alpha . \mathrm{E}\,!\,\text{max}_P\text{'}\alpha : \equiv . C\text{'}P \in \text{Cls induct}$

I.e. a series whose field is inductive is one in which every existent sub-class of the field has both a minimum and a maximum.

From the above, together with an inductive proof that every inductive class which is not a unit class is the field of some series, we obtain

***261·29.** $\vdash . \text{Cls induct} =$
$1 \cup C\text{''}\hat{P}\{P \in \text{Ser} : \alpha \subset C\text{'}P . \exists ! \alpha . \supset_\alpha . \mathrm{E}\,!\,\text{min}_P\text{'}\alpha . \mathrm{E}\,!\,\text{max}_P\text{'}\alpha\}$
$= 1 \cup C\text{''}(\Omega \cap \text{Cnv}\text{''}\Omega)$

The above proposition is interesting as giving an alternative method of treating inductive classes. Instead of the definitions adopted in *120, we might have taken the above proposition as the definition of inductive classes, putting

$$\text{NC induct} = \text{Nc}\text{''}\text{Cls induct} \quad \text{Df.}$$

We should thus wholly avoid the use of mathematical induction in definitions; hence if such avoidance were in any way desirable, it could be secured by dealing with series before introducing the distinction of finite and infinite, and then defining inductive classes as the fields of series which are well-ordered backwards as well as forwards. The inductive properties of such classes would then be deduced from *261·27, together with *260·27, in virtue of which we have

$$P \in \Omega \cap \text{Cnv}\text{''}\Omega . \supset . P = (P_1)_{\text{po}},$$

whence, by *91·62,

$$\vdash :: P \in \Omega \cap \text{Cnv}\text{''}\Omega . \supset :. xPy . \equiv : \breve{P}_1\text{''}\mu \subset \mu . \breve{P}_1\text{'}x \in \mu . \supset_\mu . y \in \mu.$$

In virtue of this proposition, if γ is the field of a well-ordered series P whose converse is well-ordered, then any property which is inherited with respect to P_1 belongs to all the successors of x (where $x \in \gamma$) if it belongs to the immediate successor of x. Hence mathematical induction follows.

From the above we obtain at once

***261·31.** $\vdash :. P \epsilon \mathrm{Ser} . \supset : C'P \epsilon \mathrm{Cls\,induct} . \equiv . P, \breve{P} \epsilon \Omega$

I.e. series whose fields are inductive are the same as inductive well-ordered series, and are also the same as well-ordered series whose converses are well-ordered. Hence also we obtain

***261·33.** $\vdash : P, Q \epsilon \Omega . Q \subseteq \breve{P} . \supset . Q \epsilon \Omega\,\mathrm{induct}$

I.e. a *descending* well-ordered series of terms chosen out of a well-ordered series must be finite. This proposition, which is due to Cantor, has been used by him in many proofs.

We have

***261·35.** $\vdash :. P \epsilon \Omega . \supset : C'P \epsilon \mathrm{Cls\,induct} - \iota'\Lambda . \equiv . \text{Ꭰ}'P_1 = \text{Ꭰ}'P . \mathrm{E} ! B'\breve{P}$

In *253·51 and following propositions we have already had the hypothesis $\text{Ꭰ}'P_1 = \text{Ꭰ}'P . \mathrm{E} ! B'\breve{P}$, which now turns out to be equivalent to the hypothesis that our series is finite and not null. Thus we have

***261·36.** $\vdash :. P \epsilon \Omega . \supset : C'P \epsilon \mathrm{Cls\,induct} - \iota'\Lambda . \equiv . \mathrm{Nr}'P \neq \dot{1} \dotplus \mathrm{Nr}'P$

*261·4 and following propositions are concerned in proving that a well-ordered series which is not inductive always contains progressions, and in deducing consequences from this. We have

***261·4.** $\vdash : P \epsilon \Omega - \Omega\,\mathrm{induct} . \supset . \{\overleftarrow{(P_1)_*}'B'P\} \upharpoonright P_1 \epsilon \mathrm{Prog}$

The above proposition is very important, for many reasons. One of its most important consequences is that, if P is a well-ordered series which is not inductive, its field contains an $\aleph_0$, and is therefore a reflexive class (*261·401). Hence a class which can be well-ordered is either inductive or reflexive (*261·43), and a well-ordered series is either inductive or infinite according to the definitions given above (*261·41). Hence where well-ordered series are concerned, the two ways of defining finite and infinite (namely those in *120 and *124) give equivalent results. This cannot (so far as is known) be proved for classes in general without assuming the multiplicative axiom.

From the above-mentioned propositions it follows that an infinite well-ordered series is one in which P_1 limited to the posterity of $B'P$ with respect to $\dot{P_1}$ is a progression in the sense of *122 (*261·44), and that any class contained in a well-ordered series is either inductive or reflexive (*261·46).

The number ends with some propositions in ordinal arithmetic. We prove that P^Q is well-ordered if P is well-ordered and Q is a finite well-ordered series (*261·62); that if R is a finite well-ordered series, and P is less than Q (in the sense of *254), then P^R is less than Q^R; and that a finite well-ordered series is less than an infinite one (*261·65).

$[*250\cdot121]\quad = C``(\Omega \cap \mathrm{Cnv}``\Omega) . \supset \vdash . \mathrm{Prop}$

The following four propositions are immediate consequences of the propositions already proved.

$*261 \cdot 3$. $\vdash :: P \in \mathrm{Ser} \,.\, \supset :.$

$$C'P \in \mathrm{Cls\ induct} \,.\, \equiv : P \in \Omega : \alpha \subset C'P \,.\, \exists ! \alpha \,.\, \supset_\alpha \,.\, E ! \max_P{}'\alpha$$

$[*261 \cdot 28 \,.\, *250 \cdot 121]$

$*261 \cdot 31$ $\vdash :. P \in \mathrm{Ser} \,.\, \supset : C'P \in \mathrm{Cls\ induct} \,.\, \equiv .\, P, \breve{P} \in \Omega$ $[*261 \cdot 3 \,.\, *250 \cdot 121]$

$*261 \cdot 32$. $\vdash .\, \mathrm{Ser} \cap \breve{C}``\mathrm{Cls\ induct} = \Omega \ \mathrm{induct} = \Omega \cap \mathrm{Cnv}``\Omega$ $[*261 \cdot 31 \cdot 14]$

On account of this proposition, we do not introduce the notation "Ser induct" for "$\mathrm{Ser} \cap \breve{C}``\mathrm{Cls\ induct}$," because a series whose field is inductive is a well-ordered series, and therefore the notation "Ω induct" gives all that is wanted.

$*261 \cdot 33$. $\vdash : P, Q \in \Omega \,.\, Q \mathrel{\subseteq\!\!\!\!\cdot\,} \breve{P} \,.\, \supset .\, Q \in \Omega \ \mathrm{induct}$

Dem.

$$
\begin{aligned}
&\vdash .\, *204 \cdot 2 \,.\, \supset \vdash : \mathrm{Hp} \,.\, \supset .\, \breve{Q} \in \mathrm{Ser} \,.\, \breve{Q} \mathrel{\subseteq\!\!\!\!\cdot\,} P \,. \\
&[*250 \cdot 14] \qquad \supset .\, \breve{Q} \in \mathrm{Ser} \cap \mathrm{Bord} \,. \\
&[*250 \cdot 12] \qquad \supset .\, \breve{Q} \in \Omega \,. \\
&[*261 \cdot 32] \qquad \supset .\, Q \in \Omega \ \mathrm{induct} : \supset \vdash .\, \mathrm{Prop}
\end{aligned}
$$

This proposition (which is due to Cantor) is of great importance in the theory of well-ordered series. It shows that, however great a well-ordered series may be, any *descending* well-ordered series contained in it must be finite. (A *descending* series in a given series is a series contained in the converse of the given series.)

$*261 \cdot 34$. $\vdash : P \in \Omega \,.\, \text{Ɑ}'P_1 = \text{Ɑ}'P \,.\, E ! B'\breve{P} \,.\, \supset .\, C'P \in \mathrm{Cls\ induct}$

Dem.

$$
\begin{aligned}
&\vdash .\, *250 \cdot 23 \,.\, *214 \cdot 12 \,.\, \supset \vdash :. \mathrm{Hp} \,.\, \alpha \subset C'P \,.\, \supset : E ! \max_P{}'\alpha \,.\, \vee \,.\, E ! \mathrm{seq}_P{}'\alpha \quad (1) \\
&\vdash .\, *206 \cdot 181 \,.\, \supset \vdash : \mathrm{Hp} \,.\, \alpha \subset C'P \,.\, \exists ! \alpha \,.\, E ! \mathrm{seq}_P{}'\alpha \,.\, \supset .\, \mathrm{seq}_P{}'\alpha \in \text{Ɑ}'P_1 \,. \\
&[*204 \cdot 7] \qquad \supset .\, E ! P_1{}'\mathrm{seq}_P{}'\alpha \,. \\
&[*206 \cdot 451] \qquad \supset .\, E ! \max_P{}'\alpha \quad (2) \\
&\vdash .\, (1) \,.\, (2) \,.\, \supset \vdash :. \mathrm{Hp} \,.\, \supset : \alpha \subset C'P \,.\, \exists ! \alpha \,.\, \supset_\alpha \,.\, E ! \max_P{}'\alpha : \\
&[*261 \cdot 3] \qquad \supset : C'P \in \mathrm{Cls\ induct} :. \supset \vdash .\, \mathrm{Prop}
\end{aligned}
$$

$*261 \cdot 35$. $\vdash :. P \in \Omega \,.\, \supset : C'P \in \mathrm{Cls\ induct} - \iota'\Lambda \,.\, \equiv .\, \text{Ɑ}'P_1 = \text{Ɑ}'P \,.\, E ! B'\breve{P}$

$[*261 \cdot 22 \cdot 24 \cdot 34]$

Observe that "$\text{Ɑ}'P_1 = \text{Ɑ}'P \,.\, E ! B'\breve{P}$" occurs as hypothesis in $*253 \cdot 51$ and some succeeding propositions. Thus this hypothesis is equivalent to the hypothesis that the field of P is an inductive existent class. It follows that

if P is an inductive well-ordered series, $\mathrm{Nr}`P_s = \mathrm{Nr}`P$, whereas if P is a well-ordered series which is not inductive, $\mathrm{Nr}`P_s = \mathrm{Nr}`P \dot{+} \dot{1}$; also that

$*262$. FINITE ORDINALS.

Summary of $*262$.

Finite ordinals are defined as the ordinals of finite well-ordered series; infinite ordinals are defined as the ordinals of infinite well-ordered series. In virtue of $*261{\cdot}42$, finite ordinals are those whose members have fields which are inductive, and are also those whose members have fields which are not reflexive. Finite ordinals have the formal properties which cardinals have but which relation-numbers and ordinals in general do not have, *i.e.* their sums and products are commutative, and the distributive law holds in the form

$$\mu \dot{\times} (\nu \dot{+} \varpi) = (\mu \dot{\times} \nu) \dot{+} (\mu \dot{\times} \varpi),$$

as well as in the form

$$(\nu \dot{+} \varpi) \dot{\times} \mu = (\nu \dot{\times} \mu) \dot{+} (\varpi \dot{\times} \mu),$$

which was proved generally in $*184{\cdot}35$.

The distinguishing properties of finite ordinals are most readily established by means of their correspondence with inductive cardinals. In general, two well-ordered series whose fields have the same cardinal need not be ordinally similar, but when the cardinal of the fields is inductive, the two series must be ordinally similar. Hence the ordinal of a *finite* well-ordered series is determined by the cardinal of the field of the series. We put generally

$$\mu_r = \Omega \cap \breve{C}\text{“}\mu \quad \text{Df.}$$

The result is that, if μ is an inductive cardinal, μ_r is the ordinal of all those series whose fields have μ members. Thus there is a one-one correspondence of inductive cardinals and finite ordinals; and in virtue of this correspondence, the formal properties of finite ordinals can be deduced from those of inductive cardinals.

It will be observed that, according to the definitions already given,

$$\vdash . \, 0_r = \Omega \cap \breve{C}\text{“}\Lambda \text{ by } *250{\cdot}43,$$

$$\vdash . \, 2_r = \Omega \cap \breve{C}\text{“}2 \text{ by } *250{\cdot}44.$$

Hence the notations 0_r, 2_r are particular cases of the general notation μ_r. But in virtue of $*200 \cdot 12$, we have, by the definition of μ_r,

$$\vdash . 1_r = \Lambda,$$

so that 1_r does not take its place in the series of finite ordinals.

Our definitions in this number are

$$\text{NO fin} = \text{N}_0\text{r}``\Omega \text{ fin} \quad \text{Df},$$

$$\text{NO infin} = \text{N}_0\text{r}``\Omega \text{ infin} \quad \text{Df},$$

$$\mu_r = \Omega \cap \breve{C}``\mu \quad \text{Df}.$$

It will be observed that for the sake of convenience we have defined NO fin and NO infin so as to exclude Λ. The definition of μ_r is chiefly useful when μ is an inductive cardinal.

The number begins with various elementary propositions, partly embodying the definitions, partly concerned with μ_r. We have

$*262 \cdot 12$. $\vdash : P \in \mu_r . \equiv . P \in \Omega . C`P \in \mu$

$*262 \cdot 18$. $\vdash : \mu \in \text{NC} . \exists ! \mu_r . \supset . \mu = C``\mu_r$

This proposition does not require that μ_r should be a relation-number. If μ is a reflexive cardinal, μ_r is not a relation-number unless it is null, because series of many different relation-numbers can be made with a given cardinal number of terms. When μ is a cardinal, "$\exists ! \mu_r$" means that classes having μ terms can be well-ordered.

$*262 \cdot 19$. $\vdash :. \mu, \nu \in \text{NC} . \exists ! \mu_r . \supset : \mu = \nu . \equiv . \mu_r = \nu_r$

Thus the relation of μ to μ_r is one-one so long as μ is the cardinal number of a class which can be well-ordered.

We next prove that if μ is an inductive cardinal other than Λ or 1, μ_r is a finite ordinal, and that every finite ordinal is of the form μ_r for an appropriate μ. We have

$*262 \cdot 21$. $\vdash : \mu \in \text{NC induct} - \iota`\Lambda - \iota`1 . \supset . \exists ! \mu_r$

$*262 \cdot 24$. $\vdash : \mu \in \text{NC induct} - \iota`\Lambda - \iota`1 . \supset . \mu_r \in \text{NO fin}$

We prove this by means of an inductive proof that two series are similar if their fields are inductive and similar.

$*262 \cdot 26$. $\vdash : \alpha \in \text{NO fin} . \equiv . (\exists \mu) . \mu \in \text{N}_0\text{C induct} - \iota`1 . \alpha = \mu_r$

Hence we easily obtain the properties of finite ordinals from those of the corresponding cardinals. Assuming that μ, ν are inductive cardinals other than 1, we have

$*262 \cdot 33$. $\mu_r \dot{+} \nu_r = (\mu +_0 \nu)_r$

$*262 \cdot 35$. $\mu_r \dot{+} \dot{1} = (\mu +_0 1)_r$, if $\mu \neq 0$,

$*262 \cdot 43$. $\mu_r \dot{\times} \nu_r = (\mu \times_0 \nu)_r$

***262·53.** $\mu_r \exp_r \nu_r = (\mu^\nu)_r$, if $\nu \neq 0$,

***262·7.** $\mu > \nu \,.\equiv.\, \mu_r > \nu_r$

Hence if α, β, γ are finite ordinals,

***262·6.** $\alpha \dot{+} \beta = \beta \dot{+} \alpha$

***262·61.** $\alpha \dot{\times} \beta = \beta \dot{\times} \alpha$

***262·62.** $\alpha \dot{\times} (\beta \dot{+} \gamma) = (\alpha \dot{\times} \beta) \dot{+} (\alpha \dot{\times} \gamma)$

***262·63.** $(\alpha \dot{\times} \beta) \exp_r \gamma = (\alpha \exp_r \gamma) \dot{\times} (\beta \exp_r \gamma)$

Thus the arithmetic of finite ordinals obeys the same formal laws as the arithmetic of inductive cardinals.

$*263$. PROGRESSIONS.

Summary of $*263$.

If R is a progression in the sense defined in $*122$, *i.e.* a one-one relation whose field is the posterity of its first term, then R_{po} is a serial relation, and the series generated by R_{po} is of the type which Cantor calls ω, *i.e.* the smallest of infinite series. It is easy to prove that all progressions are ordinally similar, and that, if all inductive cardinals exist, the series of inductive cardinals in order of magnitude is of the type ω. Thus ω is an ordinal number, which is not null if the axiom of infinity holds.

Most of the properties of ω are easily deduced from the corresponding properties of "Prog," which have been proved in $*122$. The definition is

$$\omega = \hat{P}\{(\exists R) \,.\, R \in \mathrm{Prog} \,.\, P = R_{po}\} \quad \mathrm{Df.}$$

The axiom of infinity implies that "less to greater" with its field confined to inductive cardinals is a member of ω, or, what comes to the same thing but is easier to prove, that $\{(\mathrm{NC\,induct}) \upharpoonright (+_c 1)\}_{po}$ is a member of ω ($*263 \cdot 12$). Thus the axiom of infinity for the type of x implies the existence of ω in the type $t^{33}{}^{\backprime}x$ ($*263 \cdot 132$); and generally the existence of ω in any type of relations is equivalent to the existence of $\aleph_0$ in the type of their fields ($*263 \cdot 131$), because $\aleph_0 = \mathrm{D}^{\backprime\backprime}\omega = C^{\backprime\backprime}\omega$ ($*263 \cdot 101$).

By using the fact that in a progression R (in the sense of $*122$) all the terms are values of ν_R, where every inductive cardinal occurs as a value of ν (which was proved in $*122$), we easily deduce that if there are progressions they are the series that are ordinally similar to the series of inductive cardinals ($*263 \cdot 161$). Hence both "Prog" and ω are relation-numbers ($*263 \cdot 162 \cdot 19$). Moreover, by $*122 \cdot 21 \cdot 23$, ω consists of well-ordered series ($*263 \cdot 11$). Hence ω is an ordinal number ($*263 \cdot 2$).

We next prove that progressions are infinite series ($*263 \cdot 23$), and that a series contained in a progression is finite if it has a maximum ($*263 \cdot 27$), and is a progression if it has no maximum ($*263 \cdot 26$). It follows that, assuming the existence of progressions or the axiom of infinity, ω is the smallest ordinal which is greater than all the finite ordinals ($*263 \cdot 31 \cdot 32$). Connected with this is the fact that the predecessors of any term in a progression are an inductive class ($*263 \cdot 412$).

*263·44·48 give various formulae for ω, any one of which might be taken as the definition. We have

***263·44.** $\vdash . \omega = \Omega - \iota`\Lambda \cap \hat{P}(\text{G}`P_1 = \text{G}`P . \sim E ! B`\breve{P})$

I.e. progressions are existent well-ordered series in which every term except the first has an immediate predecessor, and there is no last term.

***263·46.** $\vdash . \omega = \Omega \cap \hat{P}(E ! B`P_1 . \sim E ! B`\breve{P})$

I.e. progressions are well-ordered series in which there is only one term having an immediate successor but no immediate predecessor, and there is no last term.

***263·47.** $\vdash . \omega = \Omega \cap \hat{P}\{\alpha \subset C`P . \supset_\alpha : \alpha \in \text{Cls induct} . \equiv . \exists ! C`P \cap p`\overleftarrow{P}``\alpha\}$

I.e. a progression is a well-ordered series in which any sub-class α stops short of some point of the series if α is inductive, but not otherwise. This proposition will be useful in the next section.

***263·49.** $\vdash . \Omega \text{ fin} \cup \omega = \Omega \cap \hat{P}(\text{G}`P_1 = \text{G}`P) = \Omega \cap \hat{P}(P = P_{\text{fn}})$

I.e. finite well-ordered series and progressions together are those well-ordered series in which every term except the first has an immediate predecessor, and are also those in which every interval is an inductive class.

From *261·45 it follows that, if P is an infinite well-ordered series, P confined to the terms at a finite distance from $B`P$ is a progression, *i.e.*

***263·5.** $\vdash : P \in \Omega \text{ infin} . \supset . P \upharpoonright (\iota`B`P \cup \overleftarrow{P}_{\text{fn}}`B`P) \in \omega$

Hence it follows at once that an infinite ordinal is at least as great as ω, and therefore infinite ordinals other than ω are greater than ω, *i.e.*

***263·54.** $\vdash : \alpha \in \text{NO infin} - \iota`\omega . \supset . \alpha > \omega$

The remaining propositions of this number are occupied in proving $\omega \dot{\times} 2_r = \omega$ (*263·63) and $\omega \dot{\times} \alpha = \omega$ if α is finite and not zero (*263·66). It is not the case that $2_r \dot{\times} \omega = \omega$ or $\alpha \dot{\times} \omega = \omega$.

Cantor has varied his definitions of multiplication as regards the order of the factors. Originally, he adopted the same rule as we have adopted, but in later works he inverted the rule, so that what we call $2_r \dot{\times} \omega$ he calls $\omega \dot{\times} 2_r$, and vice versa. Thus with his definitions in his later works, $2_r \dot{\times} \omega = \omega$ but $\omega \dot{\times} 2_r \neq \omega$. We have reverted to his earlier practice, for various reasons, but chiefly in order to have $\text{Nr}`\Pi`(P \downarrow Q) = \text{Nr}`P \dot{\times} \text{Nr}`Q$ (cf. *172). Whichever rule we adopt, there are some inconveniences, so that the question as to which is chosen is not of great importance.

The proof proceeds as in $*263 \cdot 63$.

$*264$. DERIVATIVES OF WELL-ORDERED SERIES.

Summary of $*264$.

The principal purpose of the present number is to show that every infinite well-ordered series is the sum of a series of progressions followed by a finite tag, which may be null. For this purpose, we proceed as follows: If x is any member of $C\text{‘}P$, it must belong to the family, with respect to P_1, of some member of $C\text{‘}P - \text{Ɑ}\text{‘}P_1$, unless $x = B\text{‘}\breve{P}$ and $B\text{‘}\breve{P} \sim\epsilon\, \text{Ɑ}\text{‘}P_1$. Assuming that we have either $\sim E\,!\, B\text{‘}\breve{P}$ or $B\text{‘}\breve{P} \,\epsilon\, \text{Ɑ}\text{‘}P_1$, and assuming further that P is an infinite well-ordered series other than a progression, it follows that every member of $C\text{‘}P$ belongs to the family, with respect to P_1, of some member of $C\text{‘}\nabla\text{‘}P$, because, by $*216{\cdot}611$, $C\text{‘}\nabla\text{‘}P = \text{D}\text{‘}P_1 - \text{Ɑ}\text{‘}P_1$ in the circumstances contemplated ($*264{\cdot}15$). Now P limited to any one family with respect to P_1 is a progression, unless that family includes $B\text{‘}\breve{P}$; and if it includes $B\text{‘}\breve{P}$, it is finite. Hence our proposition follows.

An important consequence of the above proposition is that every cardinal which is not inductive and is applicable to classes that can be well-ordered is a multiple of $\aleph_0$ ($*264{\cdot}48$).

For the purposes of this number we need a notation for the series of series each of which consists of the family of some member of $C\text{‘}\nabla\text{‘}P$. We therefore put

$$P_{\text{pr}} = P \upharpoonright ; \overleftarrow{(P_1)_*} ; \nabla\text{‘}P \quad \text{Dft } [*264].$$

Here "pr" is intended to suggest "progression." When $P \,\epsilon\, \Omega \text{ infin} - \omega$, P_{pr} is the series of progressions (possibly ending in a finite tag) whose sum is P (or $P \upharpoonright \text{D}\text{‘}P$, in one case). Before using this definition, some preliminary considerations are necessary. $\nabla\text{‘}P$ is the series of limit-points of P, including $B\text{‘}P$. In order that $\nabla\text{‘}P$ may exist, there must be at least one limit-point besides $B\text{‘}P$. Now the limit-points of a series are $C\text{‘}P - \text{Ɑ}\text{‘}P_1$, *i.e.* the limit-points other than $B\text{‘}P$ are $\text{Ɑ}\text{‘}P - \text{Ɑ}\text{‘}P_1$ ($*216{\cdot}21$). Hence when $B\text{‘}P$ exists and $\text{Ɑ}\text{‘}P - \text{Ɑ}\text{‘}P_1$ exists, $\nabla\text{‘}P$ exists. Hence by $*263{\cdot}49$,

$*264{\cdot}13$. $\vdash :. P \,\epsilon\, \Omega \,.\supset :\, \exists\,!\, \nabla\text{‘}P \,.\equiv .\, P \,\epsilon\, \Omega \text{ infin} - \omega$

I.e. a well-ordered series whose derivative exists is one which is infinite and not a progression. We have similarly

*264·14. $\vdash : P \epsilon \Omega \operatorname{infin} - \omega . \supset . C'\nabla'P = C'P - \mathrm{Cl}'P_1$

and

*264·12. $\vdash : P \epsilon \Omega . \supset . \mathrm{Cl}'\nabla'P = \mathrm{Cl}'P - \mathrm{Cl}'P_1$

We next proceed (*264·2—·261) to study the posterity of a term x with respect to P_1, *i.e.* the series $P \upharpoonright \overleftarrow{(P_1)_*}'x$. We show that if this series has a last term, it is finite (*264·21), and ends with $B'\breve{P}$ (*264·2), while if not, and if $x \epsilon C'P_1$, *i.e.* if x has either an immediate successor or an immediate predecessor, the series is a progression (*264·22). Hence we have

*264·23. $\vdash :. P \epsilon \Omega . x \epsilon C'\nabla'P \cap C'P_1 . \supset :$

$$\mathrm{E} ! \max_P{}'\overleftarrow{(P_1)_*}'x . \equiv . x = B'\mathrm{Cnv}'\nabla'P . \mathrm{E} ! B'\breve{P}$$

Moreover, if $x \epsilon C'P_1$, the ancestry of x with respect to P_1 must end with a member of the derivative of P, *i.e.*

*264·233. $\vdash : P \epsilon \Omega \operatorname{infin} - \omega . x \epsilon C'P_1 . \supset . \min_P{}'\overrightarrow{(P_1)_*}'x \epsilon C'\nabla'P$

We thus arrive at the result that if P has a last term, so has $\nabla'P$ (*264·24), and if x is any member of the derivative except the last, the series $P \upharpoonright \overleftarrow{(P_1)_*}'x$ is a progression (*264·25), while if x is the last term of the derivative, and the series P has a last term, then $P \upharpoonright \overleftarrow{(P_1)_*}'x$ is finite (*264·252). Moreover the supposition that P ends with a member of the derivative is equivalent to the supposition that P ends with a term which has no immediate predecessor (*264·26).

We now proceed (*264·3—·403) to consider the relation P_{pr} defined above. If we take any term y in a well-ordered series, there is some term x belonging to $C'P - \mathrm{Cl}'P_1$ such that the family of y with respect to P_1 is the posterity of x. This results from *264·233 above. Thus we may divide the field of P into mutually exclusive stretches, each of which is the posterity of some member of $C'P - \mathrm{Cl}'P_1$ with respect to P_1. The series of series thus obtained is P_{pr}. There is an exceptional case, when the series ends in a term having no immediate predecessor, for then the posterity of this term with respect to P_1 is null, and therefore P_{pr} omits this term. Otherwise, we shall have $\Sigma'P_{\mathrm{pr}} = P$; *i.e.* we have

*264·39. $\vdash : P \epsilon \Omega \operatorname{infin} - \omega . \sim (B'\breve{P} \epsilon C'\nabla'P) . \supset . \Sigma'P_{\mathrm{pr}} = P$

*264·391. $\vdash : P \epsilon \Omega . B'\breve{P} \epsilon C'\nabla'P . \supset . \Sigma'P_{\mathrm{pr}} = P \upharpoonright \mathrm{D}'P$

Moreover we have

*264·36. $\vdash : P \epsilon \Omega . \supset . P_{\mathrm{pr}} \operatorname{smor} \nabla'P . P_{\mathrm{pr}} \epsilon \mathrm{Rel}^2 \operatorname{excl}$

From what was proved earlier we know that, assuming $P \epsilon \Omega$, we have $\text{D}`P_{\text{pr}} \subset \omega$ (*264·401); if $P$ has no last term, $C`P_{\text{pr}} \subset \omega$; if P is infinite and has a last term, $B`\breve{P}_{\text{pr}}$ is finite, and if the last term of $P$ belongs to $C`\nabla`P$, $B`\breve{P}_{\text{pr}} = \dot{\Lambda}$. Hence, using *251·63, which assures us that, in virtue of *264·36 above, if $C`P_{\text{pr}} \subset \omega$, $\Sigma`P_{\text{pr}}$ is a multiple of ω, we find (*264·44) that every well-ordered series has an ordinal number of the form $(\alpha \dot{\times} \omega) \dot{+} \beta$, where α and β may be any ordinals, including 0_r and $\dot{1}$ (putting $\dot{1} \dot{\times} \alpha = \alpha$ to avoid exceptional cases). The above account omits the exceptional cases, which require special treatment and render the proof long; but in the end the above simple result is obtained.

Since a multiple of $\aleph_0$ is not increased by the addition of an inductive cardinal, it follows (*264·44) that the cardinal number of the field of an infinite well-ordered series is always a multiple of $\aleph_0$ (*264·47). Hence if all classes can be well-ordered, all cardinals which are not inductive are multiples of $\aleph_0$. In virtue of Zermelo's theorem, the same result follows if the multiplicative axiom is true.

*265. THE SERIES OF ALEPHS.

Summary of *265.

In the present number, we shall confine ourselves to the most elementary properties of the ordinals and cardinals considered. The most important propositions to be proved are the existence-theorems. These all depend upon the axiom of infinity; moreover, as the numbers concerned grow greater, the existence-theorems require continually higher types.

In virtue of the definition in *262, $(\aleph_0)_r$ is the class of well-ordered series whose fields have $\aleph_0$ terms. This is not an ordinal number, but the logical sum of a certain class of ordinal numbers, namely of $\mathrm{Nr}``(\aleph_0)_r$.

ω_1 is the smallest ordinal whose field has more than $\aleph_0$ terms. We do not, however, take this as the definition of ω_1: we define ω_1 as the class of relations P such that the relations less than P (in the sense of *254) are those well-ordered series which are finite or have $\aleph_0$ terms in their fields, *i.e.*

$$\omega_1 = \hat{P}\{\overrightarrow{\mathrm{less}}`P = (\aleph_0)_r \cup \Omega\ \mathrm{fin}\} \quad \mathrm{Df.}$$

By *254·401 it follows immediately that if $P \in \omega_1$, P is a well-ordered series and ω_1 is its ordinal number (*265·11). Hence ω_1 is an ordinal number (*265·12), though we need the axiom of infinity to show that ω_1 exists.

Assuming the axiom of infinity, the existence-theorem for ω_1 is derived from the series of ordinals which are finite or belong to series of $\aleph_0$ terms For notational convenience, we temporarily define this series as N; thus

$$N = (\lessdot) \upharpoonright \{\mathrm{NO\ fin} \cup \mathrm{Nr}``(\aleph_0)_r\} \quad \mathrm{Dft}\ [*265].$$

It is also convenient temporarily to write M for "$\lessdot$": thus

$$M = \lessdot \quad \mathrm{Dft}\ [*265].$$

It is easy to prove that if $\aleph_0$ exists, N is an ω_1 (*265·25). Hence we obtain the existence-theorem for ω_1 in either of the forms:

***265·27.** $\vdash : \exists ! \aleph_0 \cap t`\alpha . \supset . \exists ! \omega_1 \cap t^{11}`t_{00}`\alpha$

***265·28.** $\vdash : \mathrm{Infin\ ax}\,(x) . \supset . \exists ! \omega_1 \cap t^{11}`t^{33}`x$

It is easy to prove that ω_1 is greater than the ordinal number of any series of $\aleph_0$ terms (*265·3), and that if ω_1 exists,

$$\overrightarrow{M}`\omega_1 = \mathrm{NO\ fin} \cup \mathrm{Nr}``(\aleph_0)_r \quad (*265{\cdot}35),$$

i.e. the ordinals less than ω_1 are those that apply to series of $\aleph_0$ terms or of a finite number of terms.

We define $\aleph_1$ as $C``\omega_1$, *i.e.* as the class of those classes which can be arranged in a series whose ordinal number is ω_1. It follows from $*152 \cdot 71$ that $\aleph_1$ so defined is a cardinal number ($*265 \cdot 33$), and that if $\aleph_0$ exists, $\aleph_1 > \aleph_0$ ($*265 \cdot 34$).

In a precisely analogous fashion we can put

$$\omega_2 = \hat{P}\{\overrightarrow{\text{less}}`P = (\aleph_1)_r \cup (\aleph_0)_r \cup \Omega \text{ fin}\} \quad \text{Df},$$

$$\aleph_2 = C``\omega_2 \quad \text{Df}.$$

Theorems similar to those mentioned above can be proved for ω_2 and $\aleph_2$ by similar methods. We can proceed to ω_ν and $\aleph_\nu$, where ν is any ordinal number. But our methods of proving existence-theorems fail if ν is not finite, since at each stage the existence-theorem is proved in a higher type and we know of no meaning that can be assigned to types whose order is not finite.

It is easy to prove that the sum of two ordinals which are less than ω_1 is less than ω_1. Much of the accepted theory of $(\aleph_0)_r$ and ω_1 depends upon the proposition that the limit of any progression of ordinals less than ω_1 is less than ω_1, so that in the series N, every progression has a limit within the series. This proposition—or at any rate the current proof of it—depends upon the multiplicative axiom. The proof, in outline, is as follows:

It is easy to prove that an ordinal which has $\aleph_0$ predecessors must be a member of $\text{Nr}``(\aleph_0)_r$, *i.e.* must be, in Cantor's language, an ordinal of the second class. Now consider any progression P contained in N, *i.e.* consider a series $\alpha_1, \alpha_2, \ldots \alpha_\nu, \ldots$ of increasing ordinals of the second class. The interval between any two consecutive terms of this series is either finite or has $\aleph_0$ terms. Hence $N``C`P$, *i.e.* the class of ordinals preceding the limit of our series, is the sum of $\aleph_0$ classes each of which is finite or has $\aleph_0$ terms. It is then argued that, because $\aleph_0 \times_c \aleph_0 = \aleph_0$, the whole class $N``C`P$ must consist of $\aleph_0$ terms. This conclusion, however, except in special cases, requires the multiplicative axiom, since it depends upon $*113 \cdot 32$, *i.e.*

$$\vdash :. \text{Mult ax} . \supset : \mu, \nu \in \text{NC} . \kappa \in \nu \cap \text{Cl.excl}`\mu . \supset . s`\kappa \in \mu \times_c \nu.$$

It follows that, unless for those who regard the multiplicative axiom as certain, it cannot be regarded as proved that ω_1 is not the limit of a progression of smaller ordinals. With this, much of the recognized theory of ordinals of the second class becomes doubtful. For example, Cantor proceeds to define a host of ordinals of the second class as the limits of given series of such ordinals. It is probable that, in regard to all the ordinals which he has defined in this way, a proof that they belong to the second class can be found, by actually arranging the finite integers in a series of the specified type. But the mere fact that they are limits of progressions of numbers of

the second class does not, of itself, suffice to prove that they are of the second class.

As another example we may mention the very interesting work of Hausdorff*, much of which is based upon the proposition that a term which is the limit of an ω_1 chosen out of a given series cannot be the limit of an ω chosen out of the same series. This proposition is a consequence of the proposition that ω_1 is not the limit of a progression of smaller ordinals, and must therefore be regarded as doubtful. Hausdorff constructs by means of it many remarkable series, for example, compact series in which no progression or regression has a limit. The existence of such series appears, however, to be open to question, unless the multiplicative axiom is assumed.

It is not improbable that a proof, independent of the multiplicative axiom, can be found for the proposition that ω_1 is not the limit of a progression; but until such a proof is forthcoming, the proposition cannot be regarded as certain.

Propositions concerning $\aleph_2$ and ω_2, and generally $\aleph_\nu$ and ω_ν, where ν is an inductive cardinal, are proved precisely as the above propositions are proved. There is not, however, so far as we know, any proof of the existence of Alephs and Omegas with infinite suffixes, owing to the fact that the type increases with each successive existence-theorem, and that infinite types appear to be meaningless.

$\vdash . (2) . (7) . (8) . \supset \vdash . \mathrm{Prop}$

***265·51.** $\vdash : \mathrm{Hp}\, *265{\cdot}48 . P \epsilon \omega_1 . \alpha \epsilon \aleph_0 \cap \mathrm{Cl}`C`P . \sim \mathrm{E} ! \max_P`\alpha . \supset . \mathrm{E} ! \mathrm{lt}_P`\alpha$

Dem.

$\vdash . *265{\cdot}5 . \supset \vdash : \mathrm{Hp} . \supset . (\exists S) . S \epsilon \omega \cap \mathrm{Rl}`P . P``C`S = \alpha$ (1)

$\vdash . (1) . *265{\cdot}48 . \supset \vdash . \mathrm{Prop}$

The following propositions follow easily.

***265·52.** $\vdash :. \mathrm{Hp}\, *265{\cdot}48 . P \epsilon \omega_1 . \supset :$

$\alpha \cap C`P \epsilon \aleph_0 \cup \mathrm{Cls\ induct} . \equiv . \exists ! C`P \cap p`\overleftarrow{P}``(\alpha \cap C`P)$ [*265·51·41]

***265·53.** $\vdash :: \mathrm{Hp}\, *265{\cdot}48 . \supset :. P \epsilon \omega_1 . \equiv :$

$P \epsilon \Omega : \alpha \cap C`P \epsilon \aleph_0 \cup \mathrm{Cls\ induct} . \equiv_\alpha . \exists ! C`P \cap p`\overleftarrow{P}``(\alpha \cap C`P)$

***265·54.** $\vdash : P \epsilon \omega_1 . \supset . \mathrm{G}`\nabla`P \subset \mathrm{lt}_P``C``(\omega \cap \mathrm{Rl}`P)$ [*265·5]

I.e. every limit-point in an ω_1 is the limit of a progression, which is what (following Hausdorff) may be conveniently called an ω-limit.

***265·55.** $\vdash : P \epsilon \omega_1 . \supset . \mathrm{G}`\nabla`P = \mathrm{lt}_P``C``(\omega \cap \mathrm{Rl}`P)$ [*265·54 . *216·602]

This proposition does not, like *265·48, assert that every progression in P has a limit, and therefore it does not require the hypothesis of *265·48.

SECTION F.

COMPACT SERIES, RATIONAL SERIES, AND CONTINUOUS SERIES.

Summary of Section F.

A *compact* series is one in which there is a term between any two, *i.e.* in which $P \subset P^2$, where P is the generating relation. We may call any relation P compact when $P \subset P^2$; then a *transitive* compact relation will be one for which $P = P^2$. Hence a serial relation P is compact whenever $P = P^2$. Compact series in general have certain properties, some of which have been already proved; but the majority of the interesting propositions in this subject come from adding some other condition besides compactness. Thus series having *Dedekindian continuity*, which have many important properties, are such as are compact and Dedekindian. *Rational* series (*i.e.* such as are ordinally similar to the series of all rational numbers, positive and negative, or, what is equivalent, to the series of rational proper fractions) are defined as such as are compact, without beginning or end, and consisting of $\aleph_0$ terms. Such series, also, have many important properties. A *continuous* series (in Cantor's sense) is a Dedekindian series containing a rational series in such a way that there are terms of the rational series between any two terms of the given series. This species of compact series also has many important properties. It consists of all series ordinally similar to the series of real numbers including 0 and ∞.

$*270$. COMPACT SERIES.

Summary of $*270$.

The propositions of the present number are mostly either obvious or repetitions of previously proved propositions. The latter are repeated here for convenience of reference.

We put $\text{comp} = \hat{P}(P \subseteq P^2)$ Df,

so that the class of compact series is $\text{Ser} \cap \text{comp}$. We have

$*270\cdot11$. $\vdash :. P \in \text{comp} . \equiv : xPy . \supset_{x,y} . \exists ! \overleftarrow{P}\text{`}x \cap \overrightarrow{P}\text{`}y$

$*270\cdot34$. $\vdash : P \in \text{trans} \cap \text{comp} . \supset . \text{s`}P = \text{sgm`}P$

The proposition $\text{s`}P_* = \text{sgm`}P_*$, which was proved in $*212$, is a particular case of the above.

$*270\cdot41$. $\vdash : P \in \text{Ser} \cap \text{comp} . \supset . \text{Nr`}P \subset \text{Ser} \cap \text{comp}$

I.e. a series which is similar to a compact series is a compact series.

$*270\cdot56$. $\vdash : P \in \text{Ser} . Q \in \Omega . \sim E ! B\text{`}\breve{P} . \sim E ! B\text{`}\breve{Q} . \supset . P^Q \in \text{Ser} \cap \text{comp}$

This proposition gives us a means of manufacturing compact series of various types, such as $\omega \exp_r \omega$, $\omega \exp_r \omega_1$, etc.

$*270\cdot01$. $\text{comp} = \hat{P}(P \subseteq P^2)$ Df

Here "comp" is an abbreviation for "compact." "Compact" series are the same as the series which Cantor calls "überall dicht."

$*270\cdot1$. $\vdash : P \in \text{comp} . \equiv . P \subseteq P^2$ [($*270\cdot01$)]

$*270\cdot11$. $\vdash :. P \in \text{comp} . \equiv : xPy . \supset_{x,y} . \exists ! \overleftarrow{P}\text{`}x \cap \overrightarrow{P}\text{`}y$ [$*270\cdot1$]

$*270\cdot12$. $\vdash : P \in \text{comp} . \equiv . \breve{P} \in \text{comp}$ [$*270\cdot11$]

$*270\cdot13$. $\vdash : P \in \text{trans} \cap \text{comp} . \equiv . P = P^2$ [$*270\cdot1 . *201\cdot1$]

$*270\cdot14$. $\vdash : P \in \text{Ser} \cap \text{comp} . \equiv . P \in \text{Rl`}J \cap \text{connex} . P = P^2 . \equiv . P \in \text{Ser} . P = P^2$ [$*270\cdot13$]

$*270\cdot15$ $\vdash : P \in \text{Ser} \cap \text{comp} . \equiv . P \in \text{Ser} . P_1 = \dot{\Lambda}$ [$*201\cdot65 . *270\cdot14$]

***270·2.** $\vdash : P \epsilon \text{comp} . \supset . \sim \exists ! \overrightarrow{\max_P}`\overrightarrow{P}`x$ [*205·25 . *270·1]

***270·201.** $\vdash : P \epsilon \text{comp} . \supset . \sim \exists ! \overrightarrow{\min_P}`\text{Q}`P . \sim \exists ! \overrightarrow{\max_P}`\text{D}`P$

Dem.

$\vdash . *37·25 . \quad \supset \vdash . \overrightarrow{\min_P}`\text{Q}`P = \breve{P}``\text{D}`P - (\breve{P}^2)``\text{D}`P \qquad (1)$

$\vdash . (1) . *270·1 . \supset \vdash : \text{Hp} . \supset . \overrightarrow{\min_P}`\text{Q}`P = \Lambda \qquad (2)$

Similarly $\quad \vdash : \text{Hp} . \supset . \overrightarrow{\max_P}`\text{D}`P = \Lambda \qquad (3)$

$\vdash . (2) . (3) . \supset \vdash .$ Prop

***270·202.** $\vdash : P \epsilon \text{comp} . \supset . \sim \exists ! \overrightarrow{\min_P}`\breve{P}``\alpha . \sim \exists ! \overrightarrow{\max_P}`P``\alpha$
[Proof as in *270·201]

***270·203.** $\vdash : P \epsilon \text{comp} . \supset . \sim \exists ! \overrightarrow{\text{seq}_P}`\iota`x$ [*206·42 . *270·1]

***270·204.** $\vdash :. P \epsilon \text{Ser} \cap \text{comp} . \text{E} ! \text{seq}_P`\alpha . \supset . \sim \text{E} ! \max_P`\alpha$
[*206·451 . *270·15]

***270·205.** $\vdash : P \epsilon \text{Ser} \cap \text{comp} . \supset . \text{lt}_P = \text{seq}_P$ [*207·1 . *270·204]

***270·21.** $\vdash : P \epsilon \text{Rl}`J \cap \text{comp} . x \epsilon C`P . \supset . x \, \text{lt}_P (\overrightarrow{P}`x)$ [*207·31 . *270·1]

***270·211.** $\vdash : P \epsilon \text{Rl}`J \cap \text{comp} . \supset . \text{D}`\text{lt}_P = C`P$ [*270·21]

Thus if a relation is compact and contained in diversity, every member of its field is a limit-point.

***270·212.** $\vdash : P \epsilon \text{connex} . \text{D}`\text{lt}_P = C`P . \supset . P \epsilon \text{comp}$

Dem.

$\vdash . *207·34 . \supset \vdash : \text{Hp} . \supset . C`P \subset - \text{Q}`(P \dot{-} P^2) .$

[*33·251] $\quad \supset . \text{Q}`(P \dot{-} P^2) = \Lambda .$

[*270·1] $\quad \supset . P \epsilon \text{comp} : \supset \vdash .$ Prop

***270·22.** $\vdash :. P \epsilon \text{Rl}`J \cap \text{connex} . \supset : P \epsilon \text{comp} . \equiv . \text{D}`\text{lt}_P = C`P . \equiv . \text{Q}`P \subset \text{D}`\text{lt}_P$
[*270·211·212 . *207·18]

***270·23.** $\vdash : P \epsilon \text{comp} - \iota`\dot{\Lambda} . \supset . P \sim \epsilon \text{Bord}$

Dem.

$\vdash . *270·201 . \supset \vdash : \text{Hp} . \supset . (\exists \alpha) . \alpha \subset C`P . \exists ! \alpha . \sim \exists ! \overrightarrow{\min_P}`\alpha .$

[*250·101] $\quad \supset . P \sim \epsilon \text{Bord} : \supset \vdash .$ Prop

***270·24.** $\vdash : P \epsilon \text{Ser} \cap \text{comp} - \iota`\dot{\Lambda} . \supset . C`P \sim \epsilon \text{Cls induct}$

Dem.

$\vdash . *270·23 . \supset \vdash : \text{Hp} . \supset . P \sim \epsilon \Omega .$

[*261·31] $\quad \supset . C`P \sim \epsilon \text{Cls induct} : \supset \vdash .$ Prop

***270·3.** $\vdash : P \epsilon \text{Ser} \cap \text{comp} . \supset . \text{sect}`P - \text{D}`P_\epsilon = P_*``C`P$
[*211·351 . *270·15]

$*270\cdot31$. $\vdash : P \epsilon \text{trans} \cap \text{comp} . \supset . \text{D}`P_\epsilon = \text{D}`(P_\epsilon \dot{\cap} I)$ [$*211\cdot51 . *270\cdot14$]

$*270\cdot32$. $\vdash : P \epsilon \text{trans} \cap \text{comp} . \supset . \overrightarrow{P}`x \epsilon \text{D}`(P_\epsilon \dot{\cap} I)$ [$*211\cdot452 . *270\cdot1$]

$*270\cdot321$. $\vdash : \overrightarrow{P}``C`P \subset \text{D}`(P_\epsilon \dot{\cap} I) . \supset . P \epsilon \text{comp}$ [$*211\cdot451 . *270\cdot1$]

$*270\cdot322$. $\vdash :. P \epsilon \text{trans} . \supset : \overrightarrow{P}``C`P \subset \text{D}`(P_\epsilon \dot{\cap} I) . \equiv . P \epsilon \text{comp}$
[$*270\cdot32\cdot321$]

$*270\cdot33$. $\vdash :. P \epsilon \text{Ser} . \supset : P \epsilon \text{comp} . \equiv . \text{G}`\text{max}_P \cap \text{G}`\text{seq}_P = \Lambda$
[$*211\cdot551 . *270\cdot14$]

$*270\cdot34$. $\vdash : P \epsilon \text{trans} \cap \text{comp} . \supset . \text{s}`P = \text{sgm}`P$ [$*270\cdot31 . (*212\cdot01\cdot02)$]

$*270\cdot35$. $\vdash :. P \epsilon \text{trans} \cap \text{connex} \cap \text{comp} . \supset : P \epsilon \text{Ded} . \equiv . \text{G}`\text{max}_P = - \text{G}`\text{seq}_P$
[$*214\cdot4 . *270\cdot13$]

$*270\cdot351$. $\vdash :. P \epsilon \text{Ser} . \supset : P \epsilon \text{comp} \cap \text{Ded} . \equiv . \text{G}`\text{max}_P = - \text{G}`\text{seq}_P$
[$*214\cdot41 . *270\cdot14$]

A series which is compact and Dedekindian is one which has Dedekindian continuity. Thus the above proposition states that a series which has Dedekindian continuity is a series such that every class has either a maximum or a sequent, but not both.

$*270\cdot352$. $\vdash : P \epsilon \text{Ser} \cap \text{comp} \cap \text{Ded} . \alpha \epsilon \text{sect}`P . \supset . \text{limax}_P`\alpha = \text{limin}_P`(C`P - \alpha)$

By means of the above proposition, compact series can be manufactured by taking series of such types as $\omega \exp_r \omega$, $\omega \exp_r \omega_1$, $\omega_1 \exp_r \omega$, etc. Any power $\alpha \exp_r \beta$ consists of compact series, if β is an ordinal having no immediate predecessor, and α is any serial number having no immediate predecessor (*i.e.* not formed by adding $\dot{1}$ to a serial number).

$*271$. MEDIAN CLASSES IN SERIES.

Summary of $*271$.

We shall call a class α a "median" class in P if $\alpha \subset C'P$ and there is a member of α between any two terms of which one has the relation P to the other. When this is the case, we have

$$xPy \,.\supset_{x,y} .\, (\exists z) \,.\, z \in \alpha \,.\, xPz \,.\, zPy,$$

i.e.
$$P \subseteq P \upharpoonright \alpha \,|\, P.$$

Thus P cannot contain any median class unless P is compact. Conversely, if P is compact, $C'P$ is a median class. Hence relations containing median classes are the same as compact relations. Median classes are important in dealing with rational and continuous series: the rationals are a median class in the series of real numbers, and the series which Cantor calls continuous are characterized by the fact that, in addition to being Dedekindian, they contain a median class which forms a series of the same type as the rationals. If P is a compact series, the class $\overrightarrow{P}``\text{Cl}'P$ is a median class in the series $\varsigma'P$ ($*271\cdot31$). This fact is used in proving that the series of segments of a rational series is a continuous series.

Our definition is

$$\text{med} = \hat{\alpha}\hat{P}\,(\alpha \subset C'P \,.\, P \subseteq P \upharpoonright \alpha \,|\, P) \quad \text{Df.}$$

Thus $\overrightarrow{\text{med}}'P$ will be the median classes of P, and "$P \in \text{Cl}'\text{med}$" means that there are median classes of P. We have $\text{Cl}'\text{med} = \text{comp}$ ($*271\cdot18$); also

$*271\cdot15$. $\vdash : \alpha \,\text{med}\, P \,.\supset .\, P, P \upharpoonright\!\!\!\!\upharpoonright \alpha \in \text{comp}$

$*271\cdot16$. $\vdash : (\alpha \cap C'P) \,\text{med}\, P \,.\equiv .\, (\alpha \cap \text{D}'P) \,\text{med}\, P \,.\equiv .\, (\alpha \cap \text{Cl}'P) \,\text{med}\, P \,.$
$\equiv .\, (\alpha \cap \text{D}'P \cap \text{Cl}'P) \,\text{med}\, P$

If P is a series, and $\alpha \subset C'P$, α is a median class when, and only when, its derivative is $\text{Cl}'P$, *i.e.*

$*271\cdot2$. $\vdash :.\, P \in \text{Ser} \,.\, \alpha \subset C'P \,.\supset : \alpha \,\text{med}\, P \,.\equiv .\, \text{Cl}'P = \delta_P{}'\alpha$

An important proposition is

$*271\cdot39$. $\vdash : P, Q \in \text{Ser} \cap \text{Ded} \,.\, \alpha \,\text{med}\, P \,.\, \beta \,\text{med}\, Q \,.\, (P \upharpoonright\!\!\!\!\upharpoonright \alpha) \,\text{smor}\, (Q \upharpoonright\!\!\!\!\upharpoonright \beta) \,.\supset .$
$P \,\text{smor}\, Q$

I.e. if P and Q are Dedekindian series, and α, β are median classes of P and Q respectively, then if $P \upharpoonright\!\!\!\!\upharpoonright \alpha$ and $Q \upharpoonright\!\!\!\!\upharpoonright \beta$ are similar, so are P and Q. This

proposition is proved by showing that P is similar to the series of segments of $P \upharpoonright \alpha$, the correlator being lt_P with its converse domain limited (*271·37). Another important proposition is

*271·4. $\vdash : S \in P \,\overline{\mathrm{smor}}\, Q \,.\, \beta \,\mathrm{med}\, Q \,.\, \supset .\, (S``\beta) \,\mathrm{med}\, P$

I.e. a correlator of P with Q correlates median classes with median classes.

The above two propositions are used in *275·3·31, which prove that two series which are continuous (in Cantor's sense) are similar, and that a series similar to a continuous series is continuous.

$*272$. SIMILARITY OF POSITION.

Summary of $*272$.

If P, Q are two serial relations, and T is a correlator which correlates some terms of $C`P$ with some terms of $C`Q$, we say that two terms x and y, of which x belongs to $C`P$ and $y$ to $C`Q$, have similar positions with respect to T if y comes after the correlates of all members of $\mathrm{D}`T$ which $x$ comes after, and $y$ comes before the correlates of all members of $\mathrm{D}`T$ which x comes before. This notion is useful for inductive definitions of correlations. If we start by correlating any two terms x_1, y_1, and take another term x_2 coming (say) after x_1, a term y_2 having similarity of position with respect to $x_1 \downarrow y_1$ must come after y_1. Suppose now we take x_3 between x_1 and x_2. Then a term y_3 having similarity of position with respect to $x_1 \downarrow y_1 \cup x_2 \downarrow y_2$ must come between y_1 and y_2; and so on. A correlation T constructed in this way will be such that $T ; Q \Subset P \,.\, \breve{T} ; P \Subset Q$. If the whole of $C`P$ and $C`Q$ can be obtained by prolonging the construction long enough, T will at last become a correlator of P and Q. This is the principle of Cantor's proof that any two rational series are similar.

As a rule, when the notion of similarity of position is useful, the relation T will be one-one, but this is not assumed in the definition. We write "$xT_{PQ}y$" for "x and y have similar positions in P and Q respectively with respect to T," or, as we may express it more shortly, "the P-position of x is T-similar to the Q-position of y." The definition is

$$T_{PQ} = \hat{x}\hat{y}\,\{x \in C`P \,.\, y \in C`Q \,.\, \mathrm{D}`T \cap \overrightarrow{P}`x \subset T``\overrightarrow{Q}`y \,.\, \mathrm{D}`T \cap \overleftarrow{P}`x \subset T``\overleftarrow{Q}`y \,.$$
$$\mathrm{D}`T \cap \iota`x \subset \overrightarrow{T}`y\} \quad \mathrm{Df.}$$

This definition states that the predecessors of x which have T-correlates are to be correlated with predecessors of y, the successors of x which have T-correlates are to be correlated with successors of y, and if x itself has a T-correlate, y is to be a T-correlate of x.

When T is a many-one relation, the definition becomes somewhat simpler. We then have

$*272{\cdot}13$. $\vdash :: T \in \mathrm{Cls} \rightarrow 1 \,.\, \supset :.\, xT_{PQ}y \,.\, \equiv :$

$$x \in C`P \,.\, y \in C`Q : z \in \mathrm{D}`T \cap \overrightarrow{P}`x \,.\, \supset_z .\, \breve{T}`zQy : z \in \mathrm{D}`T \cap \overleftarrow{P}`x \,.\, \supset_z .\, yQ\breve{T}`z :$$
$$x \in \mathrm{D}`T \,.\, \supset .\, y = \breve{T}`x$$

We have

***272·16.** $\vdash . (\mathrm{D}`T) \upharpoonleft T_{PQ} \subseteq T$

That is, a term which has a correlate cannot have similarity of position with any term except one with which it is correlated. A member of $C`P \cap \mathrm{D}`T$ will have similarity of position with its correlate (assuming $T \epsilon \mathrm{Cls} \to 1$) if $P \upharpoonleft \mathrm{D}`T \subseteq T ; Q . \breve{T}``C`P \subset C`Q$ (*272·18).

Under ordinary circumstances, a term which is not a member of $\mathrm{D}`T$ cannot have similarity of position with any member of $\mathrm{G}`T$ (*272·2). When T is many-one and its domain is contained in $C`P$, and P and Q are series, and x has no T-correlate, we have (*272·21)

$$xT_{PQ}y . \equiv : x \epsilon C`P . y \epsilon C`Q : z \epsilon \mathrm{D}`T \cap \overrightarrow{P}`x . \equiv_z . \breve{T}`zQy,$$

i.e. in this case, x and y have similar positions if the predecessors of x which have correlates are the terms whose correlates precede y. In this case, if $x \epsilon C`P$, we have (*272·212)

$$\overleftarrow{T_{PQ}}`x = C`Q \cap \hat{y} (\mathrm{D}`T \cap \overrightarrow{P}`x = T``\overrightarrow{Q}`y) = C`Q \cap \hat{y} (\mathrm{D}`T \cap \overleftarrow{P}`x = T``\overleftarrow{Q}`y).$$

We next investigate the condition for $C`P = \mathrm{D}`T_{PQ}$, *i.e.* the condition required in order that every member of $C`P$ may have similarity of position with some member of $C`Q$. A sufficient condition is

$$P, Q \epsilon \mathrm{Ser} . Q \epsilon \mathrm{comp} . T \epsilon \mathrm{Cls} \to 1 . \mathrm{D}`T \epsilon \mathrm{Cls\,induct} . P \upharpoonleft \mathrm{D}`T \subseteq T ; Q . \dot{\exists} ! Q . \breve{T}``C`P \subset \mathrm{D}`Q \cap \mathrm{G}`Q$$

as is proved in *272·34.

We next consider the reversibility of T_{PQ}, *i.e.* the condition that the converse of T_{PQ} should be $(\breve{T})_{QP}$. A sufficient condition is

$$P, Q \epsilon \mathrm{Ser} . T \epsilon 1 \to 1 . \mathrm{D}`T \subset C`P . \mathrm{G}`T \subset C`Q \quad (*272·42).$$

Finally, we have two propositions on the addition of another couple $x \downarrow y$ to T. With the above-mentioned hypothesis of *272·42, if $xT_{PQ}y$ and $T ; Q \subseteq P$, putting $W = T \cup x \downarrow y$, we shall have $P \upharpoonleft \mathrm{D}`W = W ; Q$ (*272·51), so that the hypothesis we had for T still holds for W.

The propositions of this number are in the nature of lemmas for Cantor's proof that any two rational series are similar, which is given in *273.

***272·01.** $T_{PQ} = \hat{x}\hat{y} \{x \epsilon C`P . y \epsilon C`Q . \mathrm{D}`T \cap \overrightarrow{P}`x \subset T``\overrightarrow{Q}`y . \mathrm{D}`T \cap \overleftarrow{P}`x \subset T``\overleftarrow{Q}`y . \mathrm{D}`T \cap \iota`x \subset \overrightarrow{T}`y\}$ Df

$*273$. RATIONAL SERIES.

Summary of $*273$.

A "rational series" is a series ordinally similar to the series of all positive and negative rational numbers in order of magnitude, or, what is equivalent, a series ordinally similar to the series of all rational proper fractions (0 excluded). This characteristic of rational series is not, however, the most convenient for purposes of definition. Following Cantor, we define a rational series as one which is compact, has no beginning or end, and has $\aleph_0$ terms in its field. Thus the field of a rational series can be arranged in a progression, and this is the source of the special properties which distinguish rational series from other compact series.

Rational proper fractions can be arranged in a progression in many ways, for example the following: If two fractions (in their lowest terms) have the same denominator, put the one with the smaller numerator first; if they have different denominators, put the one with the smaller denominator first. We thus obtain the series

$$\tfrac{1}{2}, \tfrac{1}{3}, \tfrac{2}{3}, \tfrac{1}{4}, \tfrac{3}{4}, \tfrac{1}{5}, \tfrac{2}{5}, \tfrac{3}{5}, \tfrac{4}{5}, \tfrac{1}{6}, \ldots.$$

This series is a progression, and contains all rational proper fractions.

Conversely, the natural numbers can be arranged in a rational series. Take, *e.g.*, the following arrangement: Express the numbers in the dyadic scale, so that every number is of the form

$$\Sigma\, 2^\mu \, (\mu \in \kappa),$$

where κ is a finite class of integers. The relation of the number to κ is one-one. Arrange the various κ's by the principle of first differences, *i.e.* form the series $M_{\mathrm{cl}} \upharpoonright (\mathrm{Cls\ induct} - \iota`\Lambda)$, where M is the relation "less than" among finite integers. The resulting series is a rational series; thus the integers are arranged in a rational series by virtue of their correlation with the classes κ. This arrangement places all the odd numbers before all the even numbers, all numbers of the form $4\nu + 2$ before all numbers of the form 4ν, and so on. If two numbers are expressed in the dyadic scale, their relative position in the series is determined by the first digit (starting from the right) which is not the same in the two numbers: the one in which this digit is 1 precedes the one in which it is 0.

The two chief propositions in regard to rational series are (1) that any two rational series are ordinally similar, (2) that if R is a progression, its finite existent sub-classes arranged by the principle of first differences form a rational series. The second of these propositions is proved by showing (a) that the finite existent sub-classes arranged by first differences form a compact series, (b) that the finite existent sub-classes arranged by *last* differences form a progression. By this means, given any progression, we can specify a relation which arranges its terms in a rational series. For if T is a correlator of our progression R with the progression

$$R_{1c} \upharpoonright (\text{Cls induct} - \iota`\Lambda),$$

then $$T \,;\, R_{cl} \upharpoonright (\text{Cls induct} - \iota`\Lambda)$$

is a rational series whose field is $C`R$. Hence rational series exist in any type in which progressions exist.

The arrangement of the finite sub-classes of a progression, with the resultant existence-theorem for rational series, will be dealt with in the following number. In the present number, we shall be concerned with the proof that any two rational series are ordinally similar.

The proof of the similarity of any two rational series is due to Cantor. It is long and rather complicated; in outline, it is as follows.

Let P, Q be two rational series, and R, S two progressions whose fields are $C`P$ and $C`Q$ respectively. Construct a series of correlations of parts of P with parts of Q on the following plan: Begin with $\dot\Lambda$, and if T is any correlation, let the next be

$$T \mathbin{\dot\cup} \text{seq}_R`\text{D}`T \downarrow \min_S`\overleftarrow{T_{PQ}}`\text{seq}_R`\text{D}`T.$$

Then the sum of all the correlations generated from $\dot\Lambda$ by this law of succession will be a correlation of P with Q. It will be seen that, if we put

$$W = \hat{X}\hat{T}\{X = \text{seq}_R`\text{D}`T \downarrow \min_S`\overleftarrow{T_{PQ}}`\text{seq}_R`\text{D}`T\},$$

the relation which is to be shown to be a correlator of P and Q is W_A, in the sense defined in $*259$. Thus we have to prove

$$W_A \in 1 \to 1 \,.\, \text{ᗡ}`W_A = C`Q \,.\, P = W_A \,;\, Q.$$

$W_A \in 1 \to 1$ results immediately from $*259{\cdot}15$.

$P \upharpoonright \text{D}`W_A = W_A \,;\, Q$ results immediately from $*259{\cdot}16$ and $*272{\cdot}51$.

Thus it remains to prove $\text{D}`W_A = C`P \,.\, \text{ᗡ}`W_A = C`Q$.

$\text{D}`W_A = C`P$ is easily proved. By induction, if T is one of the series of partial correlators, $\text{D}`T \in \text{Cls induct}$, and therefore $\text{E}\,!\,\text{seq}_R`\text{D}`T$, by $*263{\cdot}47$, and by $*272{\cdot}34$, $C`P = \text{D}`T_{PQ}$; hence $\exists\,!\,\overleftarrow{T_{PQ}}`\text{seq}_R`\text{D}`T$, and therefore, by $*250{\cdot}121$, $\text{E}\,!\,\min_S`\overleftarrow{T_{PQ}}`\text{seq}_R`\text{D}`T$. Hence T has a successor, which correlates

$\text{seq}_R\text{'}D\text{'}T$ with $\text{min}_S\text{'}\overleftarrow{T_{PQ}}\text{'seq}_R\text{'}D\text{'}T$. Hence the successor, in R, of every member of $C\text{'}R$ which has a correlate, has a correlate; hence by induction every member of $C\text{'}R$ (*i.e.* of $C\text{'}P$) has a correlate. Hence $D\text{'}W_A = C\text{'}P$.

The proof of $\text{Cl}\text{'}W_A = C\text{'}Q$ is more difficult. As before, let T be one of the series of partial correlators. We have to prove that there is a correlator which has $\text{seq}_S\text{'}\text{Cl}\text{'}T$ in its converse domain; when this is proved, the result follows by induction. To prove this, put

$$x = \text{min}_R\text{'}\overrightarrow{T_{PQ}}\text{'seq}_S\text{'}\text{Cl}\text{'}T.$$

x exists, in virtue of $*272\cdot43$. Also since $D\text{'}W_A = C\text{'}P$, it follows from $*259\cdot13$ that there is a partial correlator U such that

$$x = \text{seq}_R\text{'}D\text{'}U.$$

We then have to prove $\quad \text{seq}_S\text{'}\text{Cl}\text{'}T = \text{min}_S\text{'}\overleftarrow{U_{PQ}}\text{'}x.$

Put $y = \text{seq}_S\text{'}\text{Cl}\text{'}T$. Then $\overrightarrow{S}\text{'}y \subset \text{Cl}\text{'}T$. Hence, by $*272\cdot2$, $\overrightarrow{S}\text{'}y \cap \overleftarrow{U_{PQ}}\text{'}x = \Lambda$. Thus if $xU_{PQ}y$, it follows that $y = \text{min}_S\text{'}\overleftarrow{U_{PQ}}\text{'}x$. To prove $xU_{PQ}y$, observe that

$$T \subseteq U \,.\, U_{PQ} \subseteq T_{PQ} \,.\, P \upharpoonright D\text{'}U = U ; Q.$$

We have $u \in D\text{'}U \,.\, \supset \,.\, \sim(uT_{PQ}y)$, by $*272\cdot2$. Hence, by the definition of T_{PQ}, we have, if $u \in D\text{'}U$,

$$(\exists z) \,.\, z \in D\text{'}T \,.\, zPu \,.\, \sim(\breve{T}\text{'}zQy) \,.\, \text{v} \,.\, (\exists z) \,.\, z \in D\text{'}T \,.\, uPz \,.\, \sim(yQ\breve{T}\text{'}z).$$

In the first case, we have $(\exists z) \,.\, z \in D\text{'}T \,.\, zPu \,.\, \sim(zPx)$, because $xT_{PQ}y$ Hence, since $x \neq z$ because $x \sim \in D\text{'}T$,

$$(\exists z) \,.\, z \in D\text{'}T \,.\, zPu \,.\, xPz.$$

Similarly, in the second case,

$$(\exists z) \,.\, z \in D\text{'}T \,.\, uPz \,.\, zPx.$$

The second case is incompatible with xPu, and the first with uPx. Hence

$$xPu \,.\, \supset \,.\, (\exists z) \,.\, z \in D\text{'}T \,.\, xPz \,.\, zPu : uPx \,.\, \supset \,.\, (\exists z) \,.\, z \in D\text{'}T \,.\, uPz \,.\, zPx.$$

But, since $xT_{PQ}y$, $xPz \,.\, \supset \,.\, yQ(\breve{T}\text{'}z) \,.\, \supset \,.\, yQ(\breve{U}\text{'}z)$, because $T \subseteq U$, and since

$$P \upharpoonright D\text{'}U = U ; Q, \quad zPu \,.\, \supset \,.\, (\breve{U}\text{'}z)\, Q\, (\breve{U}\text{'}u).$$

Hence $xPu \,.\, \supset \,.\, yQ(\breve{U}\text{'}u)$, and similarly $uPx \,.\, \supset \,.\, (\breve{U}\text{'}u)\, Qy$. Hence $xU_{PQ}y$. Hence $y = \text{min}_S\text{'}\overleftarrow{U_{PQ}}\text{'}x$, and therefore y belongs to the converse domain of the next correlator after U. Hence every term of $C\text{'}Q$ belongs to the converse domain of some correlator, and therefore to $\text{Cl}\text{'}W_A$. Hence W_A correlates P and Q, and P and Q are ordinally similar.

$*273 \cdot 01.\quad \eta = \mathrm{Ser} \cap \mathrm{comp} \cap \breve{C}``\aleph_0 \cap \hat{P}\,(\mathrm{D}‘P = \reflectbox{D}‘P) \quad \mathrm{Df}$

Following Cantor, we use η for the class of rational series.

$*273 \cdot 02.\quad R_{SPQ}‘T = T \cup \mathrm{seq}_R‘\mathrm{D}‘T \downarrow \mathrm{min}_S‘\overleftarrow{T_{PQ}}‘\mathrm{seq}_R‘\mathrm{D}‘T \quad \mathrm{Dft}\ [*273]$

$*273 \cdot 03.\quad (RS)_{PQ} = \overrightarrow{(R_{SPQ})_*}‘\dot{\Lambda} \quad \mathrm{Dft}\ [*273]$

$*273 \cdot 04.\quad T_{RSPQ} = \dot{s}‘(RS)_{PQ} \quad \mathrm{Dft}\ [*273]$

T_{RSPQ} will be shown to be a correlator of P with Q when P and Q are rational series, and R and S are progressions whose fields are $C‘P$ and $C‘Q$ respectively.

$*273 \cdot 1.\quad \vdash : P \in \eta \,.\equiv .\, P \in \mathrm{Ser} \cap \mathrm{comp} \,.\, C‘P \in \aleph_0 \,.\, \mathrm{D}‘P = \reflectbox{D}‘P \quad [(*273 \cdot 01)]$

$*273 \cdot 11.\quad \vdash :. P \in \eta \,.\equiv :\, P \in \mathrm{Ser} \cap \mathrm{comp} \,.\, \mathrm{D}‘P = \reflectbox{D}‘P : (\exists R) \,.\, R \in \omega \,.\, C‘P = C‘R$
$[*273 \cdot 1 \,.\, *263 \cdot 101]$

$*273 \cdot 2.\quad \vdash : W = \hat{X}\hat{T}\{X = \mathrm{seq}_R‘\mathrm{D}‘T \downarrow \mathrm{min}_S‘\overleftarrow{T_{PQ}}‘\mathrm{seq}_R‘\mathrm{D}‘T\} \,.\supset .$
$R_{SPQ} = A_W \,.\, (RS)_{PQ} \subset (A_W * A)‘\dot{\Lambda} \,.\, T_{RSPQ} \,\dot{\subset}\, W_A \,.\, T_{RSPQ} \in (A_W * A)‘\dot{\Lambda}$

whence $\vdash : \alpha \in \mathrm{NR} \cap \mathrm{Cl}{}^{\epsilon}\mathrm{Ser} \,.\, C{}^{\epsilon\epsilon}\alpha = \aleph_0 \,.\supset .\, \alpha \dot{\times} \eta = \eta\,;$

and

$$\vdash : P \in \eta \,.\, Q \in \mathrm{Ser} \cap \breve{C}{}^{\epsilon\epsilon}\aleph_0 \,.\, x \in C{}^{\epsilon}P \,.\supset .\, x \downarrow {}^{;}Q \in \mathrm{Nr}{}^{\epsilon}Q \cap \mathrm{Rl}{}^{\epsilon}(Q \times P) \,.\, Q \times P \in \eta,$$

whence, from the fact that all η's are similar,

$$\vdash : P \in \eta \,.\, Q \in \mathrm{Ser} \cap \breve{C}{}^{\epsilon\epsilon}\aleph_0 \,.\supset .\, \exists\,!\, \mathrm{Nr}{}^{\epsilon}Q \cap \mathrm{Rl}{}^{\epsilon}P.$$

Thus an η contains series of all the order-types composed of $\aleph_0$ terms.

$*274$. ON SERIES OF FINITE SUB-CLASSES OF A SERIES.

Summary of $*274$.

In the present number, we shall be concerned with the construction of a rational series consisting of the finite existent sub-classes of a progression. When the finite sub-classes of a progression (excluding Λ) are arranged by the principle of first differences, the result is a rational series. When they are arranged by the principle of last differences, the result is a progression. These two propositions, with the consequent existence-theorems, are to be proved in the present number.

We define "P_η" as P_{cl} with its field limited to finite existent classes. (For the definition of P_{cl}, see $*170{\cdot}01$.) In the present number, we shall be chiefly concerned with P_η when $P \epsilon \omega$, but it has interesting properties in many other cases.

Our definition is

$$P_\eta = P_{\text{cl}} \upharpoonright (\text{Cls induct} - \iota`\Lambda) \quad \text{Df.}$$

We shall be concerned in this number not only with P_η, but also with $P_{\text{1c}} \upharpoonright (\text{Cls induct} - \iota`\Lambda)$. This is $\text{Cnv}`(\breve{P})_\eta$. Thus if we put $\breve{P} = Q$, the hypothesis that $P \epsilon \Omega$ as used in studying $P_{\text{1c}} \upharpoonright (\text{Cls induct} - \iota`\Lambda)$ is equivalent to the hypothesis that $\breve{Q} \epsilon \Omega$ as used in studying $\text{Cnv}`Q_\eta$, *i.e.* $\breve{Q}_\eta$. Thus the study of P_{cl} and P_{1c} with their fields limited to inductive existent classes may be replaced by the study of P_η in the two cases where (1) $P \epsilon \Omega$, (2) $\breve{P} \epsilon \Omega$. The second case is the simpler, and is considered first. We have first, however, a collection of propositions which only assume that P is a series.

Since an inductive existent class in a series must have a maximum and a minimum, we have

$*274{\cdot}12$. $\vdash :: P \epsilon \text{Ser} . \supset :. \alpha P_\eta \beta . \equiv :$

$$\alpha, \beta \epsilon \text{Cl induct}`C`P - \iota`\Lambda : (\exists z) . z \epsilon \alpha - \beta . \alpha \cap \overrightarrow{P}`z = \beta \cap \overrightarrow{P}`z$$

We have

$*274{\cdot}17$. $\vdash : C`P \sim \epsilon 1 . \supset . C`P_\eta = \text{Cl induct}`C`P - \iota`\Lambda$

Whenever P is a series, P_η is a series (*274·18). If P has a last term, the class consisting of this last term only is the last term of P_η; if P has no last term, P_η has no last term (*274·191). If $C'P$ is an inductive existent class, the first term of P_η is $C'P$ (*274·194); if not, P_η has no first term (*274·195). Hence if P has no last term, P_η has no first or last term, and we have $\mathrm{D}'P_\eta = \mathrm{G}'P_\eta$ (*274·196). Thus of the characteristics used in defining η, we have $P_\eta \epsilon \mathrm{Ser}$ whenever $P \epsilon \mathrm{Ser}$, and $\mathrm{D}'P_\eta = \mathrm{G}'P_\eta$ whenever $\sim \mathrm{E} ! B'\breve{P}$

We next prove

***274·22.** $\vdash : \breve{P} \epsilon \Omega \,.\, \supset .\, \breve{P}_\eta \epsilon \Omega$

which, in virtue of what was said above, is equivalent to

$$P \epsilon \Omega \,.\, \supset .\, P_{\mathrm{lc}} \upharpoonright (\mathrm{Cls\ induct} - \iota'\Lambda) \epsilon \Omega,$$

that is: The principle of last differences applied to the inductive existent sub-classes of any well-ordered series gives a well-ordered series.

To prove *274·22, since we already know that P_η is a series, we only have to prove that every existent sub-class of $C'P_\eta$ has a maximum with respect to P_η. This is proved as follows.

Let κ be any existent sub-class of $\mathrm{Cl\,induct}'C'P - \iota'\Lambda$. Consider the minima of all the members of κ: these minima all exist, because κ is composed of inductive classes. Then in virtue of the nature of the principle of first differences, members of κ which have a later minimum come later than those that have an earlier minimum. Hence if we consider $\mathrm{min}_P``\kappa$, the classes whose minimum is the maximum of $\mathrm{min}_P``\kappa$ (which exists, because $\breve{P} \epsilon \Omega$) are later than any other members of κ. Put

$$x_1 = \mathrm{max}_P`\mathrm{min}_P``\kappa \,.\, \kappa_1 = \kappa \cap \overleftarrow{\mathrm{min}_P}`x_1.$$

Thus κ_1 consists of those members of κ which have the largest minimum, and members of κ_1 come later than any other members of κ. Similarly the latest members of κ_1 will be those that have the greatest second term. That is, if we take away the (common) first term from each member of κ_1, and if λ_1 is the resulting class of classes, we have to apply to λ_1 precisely the same process as we have already applied to κ. Thus we are led to put

$$x_1 = \mathrm{max}_P`\mathrm{min}_P``\kappa \,.\, \kappa_1 = \kappa \cap \overleftarrow{\mathrm{min}_P}`x_1 \,.\, \lambda_1 = (-\iota`x_1)``\kappa_1,$$
$$x_2 = \mathrm{max}_P`\mathrm{min}_P``\lambda_1 \,.\, \kappa_2 = \lambda_1 \cap \overleftarrow{\mathrm{min}_P}`x_2 \,.\, \lambda_2 = (-\iota`x_2)``\kappa_2,$$

and so on. The series $x_1, x_2, \ldots$ is an ascending series in P, and is therefore finite, by *261·33. It therefore has a last term, say x_ν. Then the class $\iota`x_1 \cup \iota`x_2 \cup \ldots \cup \iota`x_\nu$ is a member of κ, and is easily shown to be its maximum. Hence every existent sub-class κ of $C'P_\eta$ has a maximum, and therefore $\breve{P}_\eta \epsilon \Omega$.

In order to symbolize the above process, we put

$$P_m{}^\backprime\kappa = \max_P{}^\backprime\min_P{}^{\backprime\backprime}\kappa \qquad \text{Dft,}$$

$$\breve{T}_P{}^\backprime\kappa = (-\iota^\backprime P_m{}^\backprime\kappa)^{\backprime\backprime}(\kappa \cap \overleftarrow{\min_P}{}^\backprime P_m{}^\backprime\kappa) - \iota^\backprime\Lambda \qquad \text{Dft,}$$

$$M_P{}^\backprime\kappa = P_m{}^{\backprime\backprime}\overleftarrow{(\breve{T}_P)_*}{}^\backprime\kappa \qquad \text{Dft.}$$

Then $P_m{}^\backprime\kappa$ is what we called x_1, $\breve{T}_P{}^\backprime\kappa$ is what we called λ_1, $\overleftarrow{(\breve{T}_P)_*}{}^\backprime\kappa$ is the class $\kappa, \lambda_1, \lambda_2, \ldots \lambda_{\nu-1}$, and $M_P{}^\backprime\kappa$ is the class $x_1, x_2, x_3, \ldots x_\nu$. Thus what we have to prove is

$$M_P{}^\backprime\kappa = \max(P_\eta)^\backprime\kappa,$$

which is proved in $*274\cdot215$.

We prove next

$*274\cdot25.$ $\vdash : \breve{P} \epsilon \omega . \supset . \breve{P}_\eta \epsilon \omega$

For this purpose we use $*263\cdot44$, namely

$$\omega = \Omega - \iota^\backprime\Lambda \cap \hat{P}(\mathrm{G}^\backprime P_1 = \mathrm{G}^\backprime P . \sim \mathrm{E}\,!\, B^\backprime\breve{P}).$$

Thus it only remains to prove

$$\mathrm{D}^\backprime(P_\eta)_1 = \mathrm{D}^\backprime P_\eta . \sim \mathrm{E}\,!\, B^\backprime P_\eta.$$

$\sim \mathrm{E}\,!\, B^\backprime P_\eta$ follows from $*274\cdot195$, and $\mathrm{D}^\backprime(P_\eta)_1 = \mathrm{D}^\backprime P_\eta$ is proved without any difficulty; hence our proposition follows.

From $*274\cdot25\cdot17$, by substituting P for $\breve{P}$, we obtain

$*274\cdot26.$ $\vdash : P \epsilon \omega . \supset . P_{1c} \upharpoonright (\text{Cls induct} - \iota^\backprime\Lambda) \epsilon \omega .$

$$C^\backprime P_{1c} \upharpoonright (\text{Cls induct} - \iota^\backprime\Lambda) = \text{Cl induct}^\backprime C^\backprime P - \iota^\backprime\Lambda$$

whence it follows immediately that

$*274\cdot27.$ $\vdash : \alpha \epsilon \aleph_0 . \supset . \text{Cl induct}^\backprime\alpha \epsilon \aleph_0 . \text{Cl induct}^\backprime\alpha - \iota^\backprime\Lambda \epsilon \aleph_0$

I.e. a class of $\aleph_0$ terms contains $\aleph_0$ inductive sub-classes.

We now have to prove

$*274\cdot33.$ $\vdash : P \epsilon \omega . \supset . P_\eta \epsilon \eta$

In virtue of $*274\cdot17\cdot27$, we have $C^\backprime P_\eta \epsilon \aleph_0$; and by $*274\cdot18$, $P_\eta \epsilon \text{Ser}$. Thus it only remains to prove $P_\eta \epsilon \text{comp} . \mathrm{D}^\backprime P_\eta = \mathrm{G}^\backprime P_\eta$. The second of these results immediately from $*274\cdot196$. As for $P_\eta \epsilon$ comp, if $\alpha P_\eta \beta$, $\alpha \cup \beta \epsilon \text{Cls induct}$, and therefore $\exists\,!\, p^\backprime\overleftarrow{P}^{\backprime\backprime}(\alpha \cup \beta)$; but if $x \epsilon p^\backprime\overleftarrow{P}^{\backprime\backprime}(\alpha \cup \beta)$, we have $\alpha P_\eta (\beta \cup \iota^\backprime x) . (\beta \cup \iota^\backprime x) P_\eta \beta$; hence $P_\eta \subseteq P_\eta{}^2$. This completes the proof that $P_\eta \epsilon \eta$.

The proposition holds not only if $P \epsilon \omega$, but if P is any series which has no last term and whose field has $\aleph_0$ terms ($*274\cdot32$).

Finally, we deal with the existence of η ($*274\cdot4$—$\cdot46$). If $P \epsilon \omega$, P is similar to $P_{1c} \upharpoonright (\text{Cls induct} - \iota^\backprime\Lambda)$, by $*274\cdot26$; and if T is a correlator of

these two, $T \mathbin{;} P_\eta$ is an η whose field is $C\text{‘}P$ (*274·4). Hence the existence of η in any type is equivalent to the existence of ω in that type (*274·41). Hence we have merely to apply previous propositions on the existence of ω.

$*275$. CONTINUOUS SERIES.

Summary of $*275$.

The definition of continuity to be given in this number is due to Cantor. A different and not equivalent definition was given by Dedekind: series which are continuous in Cantor's sense are also continuous in Dedekind's sense, but not vice versa. Cantor's definition has the advantage (among others) that two series which are continuous in his sense are ordinally similar, which is not necessarily the case with series that are continuous in Dedekind's sense. Dedekind's definition of "continuous series" is, in our language, "series which are compact and Dedekindian." Cantor's definition (after a certain amount of simplification) is "series which are Dedekindian and contain an $\aleph_0$ as a median class." In the case of the real numbers, the rationals are a median class of this sort.

An equivalent definition to the above is that a continuous series is a Dedekindian series whose converse domain is the derivative of a contained rational series ($*275{\cdot}13$).

Following Cantor, we shall use θ for the class of continuous series.

In what follows, we prove first that the series of segments of a rational series is a continuous series, *i.e.*

$*275{\cdot}21$. $\vdash : P \epsilon \eta . \supset . \text{ς}`P \epsilon \theta$

The contained $\aleph_0$ is $\overrightarrow{P}``C`P$. The proposition follows at once from $*271{\cdot}31$. On its importance, see remarks on $*275{\cdot}21$ below.

From this proposition, it follows that if η exists in any type, θ exists in the next type ($275{\cdot}22$), whence the existence of θ in sufficiently high types follows from the axiom of infinity ($*275{\cdot}25$).

To prove that any two continuous series are similar, we use $*271{\cdot}39$. By the definition, if P and Q are continuous, they contain respectively two median classes α and β, such that $P \restriction \alpha$ and $Q \restriction \beta$ are rational series. Hence by $*273{\cdot}4$, $P \restriction \alpha \,\text{smor}\, Q \restriction \beta$, and therefore $P \,\text{smor}\, Q$, by $*271{\cdot}39$. Also obviously $P \epsilon \theta . P \,\text{smor}\, Q . \supset . Q \epsilon \theta$. Hence

***275·21.** $\vdash : P \epsilon \eta . \supset . \varsigma`P \epsilon \theta$ [*275·2·1]

This proposition is of great importance, particularly in the theory of real numbers. We shall define the real numbers as segments of the series of rational numbers, in order to be sure of their existence. Thus if P is the series of rational numbers, $\varsigma`P$, which may be taken to be the series of real numbers, is continuous. If $P$ is the series of rational proper fractions, excluding 0, $\varsigma`P$ is the series of real proper fractions together with 0 and 1: this series is continuous in virtue of the above proposition.

The above proposition is also useful as enabling us to deduce the existence of θ from that of η, and thence from that of $\aleph_0$, and thence from the axiom of infinity. A rise of type is, however, required for the existence-theorems, which are given in the following propositions.

$*276$. ON SERIES OF INFINITE SUB-CLASSES OF A SERIES.

Summary of $*276$.

The subject of the present number bears the same relation to θ as that of $*274$ bears to η. We shall consider, in the present number, the arrangement of all the *infinite* sub-classes of a series (together with Λ) by the principle of first differences, *i.e.* the relation

$$P_{\mathrm{cl}} \upharpoonright (-\,\mathrm{Cls\,induct} \cup \iota`\Lambda),$$

where P is the given series. This relation we will call P_θ. It consists of P_{cl} with its field limited to terms not belonging to $C`P_\eta$ ($*276\cdot12$). It will (under a certain hypothesis) contain a part similar to $\breve{P}_\eta$, namely $P_{\mathrm{cl}}$ with its field limited to complements of finite sub-classes of $C`P$. Hence if $P \in \omega$, P_θ will contain an η, whose field is composed of the complements of members of $C`P_\eta$ ($*276\cdot2$). The field of this η will be a median class of P_θ. We shall find, also, that $P_\theta \in \mathrm{Ser}$, if $P \in \Omega$ ($*276\cdot14$), and $P_\theta \in \mathrm{Ded}$, if $P \in \Omega\,\mathrm{infin}$ ($*276\cdot4$). Hence

$*276\cdot41$. $\vdash : P \in \omega \,.\supset .\, P_\theta \in \theta$

Also, since $P \in \omega \,.\supset .\, \mathrm{Cl}`C`P \in 2^{\aleph_0}$, and since $C`P_\eta \in \aleph_0$, we shall have $C`P_\theta \in 2^{\aleph_0}$ ($*276\cdot42$). This result is important, since it gives the proposition

$*276\cdot43$. $\vdash .\, C``\theta = 2^{\aleph_0}$

The proof that P_θ is Dedekindian if P is an infinite well-ordered series is somewhat complicated. We proceed by proving that every sub-class of $C`P_\theta$ has a lower limit or a minimum. In this proof, we observe first of all that

$$C`P = B`P_\theta \,.\, \Lambda = B`\breve{P}_\theta \quad (*276\cdot121).$$

Hence $C`P$ is the lower limit of the null-class, and $\Lambda$ is the minimum of $\iota`\Lambda$; also if κ is any existent sub-class of $C`P_\theta$, other than $\iota`\Lambda$, we have

$$\overrightarrow{\mathrm{limin}}\,(P_\theta)`\kappa = \overrightarrow{\mathrm{limin}}\,(P_\theta)`(\kappa - \iota`\Lambda).$$

Hence if we can prove

$$\kappa \subset C`P_\theta \,.\, \exists!\,\kappa \,.\, \Lambda \sim\in \kappa \,.\supset_\kappa .\, E!\,\mathrm{limin}\,(P_\theta)`\kappa \qquad (\mathrm{A}),$$

we shall have $\qquad \mathrm{Cl\,ex}`C`P_\theta \subset \mathrm{Cl}`\mathrm{limin}\,(P_\theta)$,

whence, by $*214 \cdot 12 \cdot 14$, we shall have $P_\theta \in \text{Ded}$. Thus we have to prove (A), *i.e.* $\kappa \subset D`P_\theta . \exists ! \kappa . \supset_\kappa . E ! \text{limin}(P_\theta)`\kappa$, which is $*276 \cdot 39$. To prove this proposition, consider $\text{min}_P`(s`\kappa - p`\kappa)$. This exists unless $\kappa \in 1$; it is the first term which belongs to some members of $\kappa$ but not to others. Those members of $\kappa$ to which it belongs precede (in the order $P_\theta$) those to which it does not belong. Let us call those to which it belongs $\breve{T}_P`\kappa$, so that

$$T_P = \hat{\kappa}\hat{\lambda}\{\lambda = \kappa \cap \overleftarrow{\epsilon}`\text{min}_P`(s`\kappa - p`\kappa)\}.$$

Put also $$P_m`\kappa = \text{min}_P`(s`\kappa - p`\kappa) \quad \text{Dft},$$

so that we may put $$\breve{T}_P`\kappa = \kappa \cap \overleftarrow{\epsilon}`P_m`\kappa \quad \text{Dft}.$$

Then if we put $A = \hat{\kappa}\hat{\lambda}(\lambda \subset \kappa . \lambda \neq \kappa)$, T_P and A fulfil the hypotheses of $*258$, and we have

$$A(T_P, \kappa) \in \Omega.$$

The series $A(T_P, \kappa)$ proceeds to smaller and smaller sub-classes of κ, of which any one, say λ, consists of terms which come earlier (in the order P_θ) than any other sub-class of κ not belonging to λ. By $*258 \cdot 231$, the series $A(T_P, \kappa)$ has an end, namely

$$p`(T_P * A)`\kappa.$$

If this is not null, it must consist of a single term, which will be the minimum of κ ($*276 \cdot 33$). But if it is null, we proceed as follows. Put

$$P_{tl}`\kappa = s`\hat{\gamma}\{(\exists\lambda) . \lambda \in (T_P * A)`\kappa . \gamma = p`\lambda \cap \overrightarrow{P}`P_m`\lambda\} \quad \text{Dft}.$$

Then $P_{tl}`\kappa$ will be the lower limit of κ.

In the first place, we easily prove that, since $p`(T_P * A)`\kappa = \Lambda$, if

$$\lambda \in (T_P * A)`\kappa - \iota`\Lambda,$$

$P_m`\lambda$ and $\breve{T}_P`\lambda$ both exist ($*276 \cdot 341$). Hence every member of κ has predecessors in κ, and κ has no minimum. In the second place, we show that

$$\lambda \{A(T_P, \kappa)\} \mu . \exists ! \mu . \supset . (P_m`\lambda) P (P_m`\mu) \quad (*276 \cdot 34 \cdot 342),$$

and that $$\alpha \in \lambda . \supset . p`\lambda \cap \overrightarrow{P}`P_m`\lambda = \alpha \cap \overrightarrow{P}`P_m`\lambda \quad (*276 \cdot 353).$$

Hence we find that

$$\begin{aligned} \lambda \{A(T_P, \kappa)\} \mu . \alpha \in \mu . \supset . \; & p`\lambda \cap \overrightarrow{P}`P_m`\lambda = p`\mu \cap \overrightarrow{P}`P_m`\lambda = \alpha \cap \overrightarrow{P}`P_m`\lambda . \\ \supset . \; & p`\lambda \cap \overrightarrow{P}`P_m`\lambda \subset p`\mu \cap \overrightarrow{P}`P_m`\mu . \\ & (p`\mu \cap \overrightarrow{P}`P_m`\mu) \cap \overrightarrow{P}`P_m`\lambda = p`\lambda \cap \overrightarrow{P}`P_m`\mu, \end{aligned}$$

whence it follows that

$$\lambda \in (T_P * A)`\kappa - \iota`\Lambda . \supset . p`\lambda \cap \overrightarrow{P}`P_m`\lambda = P_{tl}`\kappa \cap \overrightarrow{P}`P_m`\lambda,$$

whence, by what was stated above,

$$\lambda \in (T_P * A)`\kappa . \alpha \in \lambda . \supset . \alpha \cap \overrightarrow{P}`P_m`\lambda = P_{tl}`\kappa \cap \overrightarrow{P}`P_m`\lambda \quad (*276 \cdot 354).$$

Again, if $\alpha \epsilon \kappa$, the product of all the members of $(T_P * A)`\kappa$ to which $\alpha$ belongs is a member of $(T_P * A)`\kappa$ to which α belongs, but if we call this product λ, $P_m`\lambda \sim\epsilon\, \alpha$ (because, if $P_m`\lambda \epsilon \alpha$, $\alpha \epsilon \breve{T}_P`\lambda$, which is contrary to the definition of λ). Hence we have

$$\alpha \epsilon \kappa \,.\supset.\, (P_{\text{tl}}`\kappa) P_\theta \alpha \quad (*276\cdot36).$$

It only remains to prove

$$(P_{\text{tl}}`\kappa) P_\theta \beta \,.\supset.\, (\exists \alpha) \,.\, \alpha \epsilon \kappa \,.\, \alpha P_\theta \beta \quad (*276\cdot37).$$

By the hypothesis, and the definition of $P_{\text{tl}}`\kappa$, we have

$$(\exists z, \lambda) \,.\, \lambda \epsilon (T_P * A)`\kappa \,.\, z \epsilon p`\lambda \cap \overrightarrow{P}`P_m`\lambda - \beta \,.\, P_{\text{tl}}`\kappa \cap \overrightarrow{P}`z = \beta \cap \overrightarrow{P}`z.$$

Since this involves $\text{E}\,!\, P_m`\lambda$, it involves $\lambda \neq \Lambda$, hence, by what was stated above, it involves

$$(\exists z, \lambda, \alpha) \,.\, \lambda \epsilon (T_P * A)`\kappa \,.\, \alpha \epsilon \lambda \,.\, z \epsilon \alpha \cap \overrightarrow{P}`P_m`\lambda - \beta \,.\, P_{\text{tl}}`\kappa \cap \overrightarrow{P}`z = \beta \cap \overrightarrow{P}`z.$$

Hence we obtain $\qquad \beta \cap \overrightarrow{P}`z \subset P_{\text{tl}}`\kappa \cap \overrightarrow{P}`P_m`\lambda,$

and $\qquad P_{\text{tl}}`\kappa \cap \overrightarrow{P}`P_m`\lambda = \alpha \cap \overrightarrow{P}`P_m`\lambda,$

whence $\qquad \beta \cap \overrightarrow{P}`z \subset \alpha.$

Hence, by $*170\cdot11$, we have $\alpha P_\theta \beta$.

This completes the proof of $P_{\text{tl}}`\kappa = \text{tl}\,(P_\theta)`\kappa$ ($*276\cdot38$). Hence, combining the two cases, we find that κ has a minimum if $\exists\,!\, p`(T_P * A)`\kappa$, and a lower limit if $\sim\exists\,!\, p`(T_P * A)`\kappa$. Hence $\text{E}\,!\, \text{limin}\,(P_\theta)`\kappa$, in either case ($*276\cdot39$).

This completes the proof of $P_\theta \epsilon \text{Ded}$ if $P \epsilon \Omega\,\text{infin}$.

The propositions proved in the present number are capable of being to some extent generalized. Also we can prove

$$\vdash .\, \theta = (\omega \,\mathrm{exp}_r\, \omega) \dotplus \dot{1}.$$

For this purpose, we prove first that if P, Q are well-ordered series, P^Q is Dedekindian (except that if $\sim \mathrm{E} ! B`\breve{P}$, P^Q has no last term); *i.e.* we prove

$$P, Q \epsilon \Omega \,.\, \supset : \lambda \subset C`P^Q \,.\, \exists ! \lambda \,.\, \supset_\lambda \,.\, \mathrm{E} ! \operatorname{limin}(P^Q)`\lambda.$$

For this purpose, assuming $\lambda \subset C`P^Q \,.\, \exists ! \lambda$, put

$$Q_m`\lambda = \min_Q`\hat{y}\,(\dot{s}`\overrightarrow{\lambda}`y \sim \epsilon\, 0 \cup 1),$$
$$\breve{T}_P`\lambda = \lambda \cap \hat{M}\,\{M`Q_m`\lambda = \min_P`\dot{s}`\overrightarrow{\lambda}`Q_m`\lambda\},$$
$$A = \hat{\lambda}\hat{\mu}\,(\mu \subset \lambda \,.\, \mu \neq \lambda),$$
$$(PQ)`\lambda = \dot{s}`\hat{N}\,\{(\exists\mu) \,.\, \mu \,\epsilon\, (T_P * A)`\lambda \,.\, N = (\dot{p}`\mu) \upharpoonright \overrightarrow{Q}`Q_m`\mu\}.$$

We can then show, by steps closely analogous to those in the proof of $P_\theta \epsilon \mathrm{Ded}$, that we have

$$\exists ! p`(T_P * A)`\lambda \,.\, \supset \,.\, \breve{\iota}`p`(T_P * A)`\lambda = \min(P^Q)`\lambda,$$
$$\sim \exists ! p`(T_P * A)`\lambda \,.\, \supset \,.\, (PQ)`\lambda = \operatorname{prec}(P^Q)`\lambda,$$

whence, in either case, $\mathrm{E} ! \operatorname{limin}(P^Q)`\lambda$.

Hence we have

$$\vdash : P, Q \epsilon \Omega \,.\, \mathrm{E} ! B`\breve{P} \,.\, \supset \,.\, P^Q \epsilon \mathrm{Ded},$$
$$\vdash : P, Q \epsilon \Omega \,.\, \sim \mathrm{E} ! B`\breve{P} \,.\, Z \sim \epsilon\, C`P^Q \,.\, \supset \,.\, P^Q \dashrightarrow Z \,\epsilon\, \mathrm{Ded}.$$

We have therefore $\quad \vdash . (\omega \exp_r \omega) \dot{+} \dot{1} \subset \mathrm{Ded}.$

We now have to prove

$$Q \,\epsilon\, (\omega \exp_r \omega) \dot{+} \dot{1} \,.\, \supset \,.\, \exists ! \aleph_0 \cap \overrightarrow{\mathrm{med}}`Q.$$

For this purpose, it will be sufficient to prove

$$P \,\epsilon\, \omega \,.\, \supset \,.\, \exists ! \aleph_0 \cap \overrightarrow{\mathrm{med}}`(P^P).$$

The $\aleph_0$ in question will be the class of those members of $C`(P^P)$ in which, from a certain point onward, the correlate of every member of $C`P$ is $B`P$. We have

$$M(P^P)N \,.\, \equiv : M, N \,\epsilon\, (C`P \uparrow C`P)_\Delta`C`P :$$
$$(\exists x) \,.\, x \,\epsilon\, C`P \,.\, M \upharpoonright \overrightarrow{P}`x = N \upharpoonright \overrightarrow{P}`x \,.\, (M`x)\, P\, (N`x).$$

Now consider the relation

$$L = M \upharpoonright \overrightarrow{P_*}`x \cup y \downarrow \breve{P}_1`x \cup (\iota`B`P) \uparrow \overleftarrow{P}`\breve{P}_1`x,$$

where $(M`\breve{P}_1`x)\, Py$.

Then $M(P^P)L \,.\, L(P^P)N$. Also L has $B`P$ for the correlate of every term after $\breve{P}_1`x$. Hence it is determined by the correlates of the terms up to and including $\breve{P}_1`x$. Thus, putting $z = \breve{P}_1`x$, we have to consider the class of relations

$$\mu = \hat{X}\,\{(\exists z) \,.\, z \,\epsilon\, \mathrm{G}`P \,.\, X \,\epsilon\, 1 \rightarrow \mathrm{Cls} \,.\, \mathrm{G}`X = \overrightarrow{P_*}`z \,.\, \mathrm{D}`X \subset C`P\}.$$

If $X \epsilon \mu$, $X \cup (\iota`B`P) \uparrow \overleftarrow{P}`\max_P`\mathrm{C\!\!\!I}`X$ is a member of $C`P^P$. We have therefore only to show that $\mu \epsilon \aleph_0$.

To show that $\mu \epsilon \aleph_0$, we observe that if $X \epsilon \mu$, $\mathrm{D}`X$ and $\mathrm{C\!\!\!I}`X$ are both inductive classes; hence each has a maximum. Let X and X' be two members of μ, and let us put

$$x = \max_P`\mathrm{D}`X \,.\, x' = \max_P`\mathrm{D}`X' \,.\, y = \max_P`\mathrm{C\!\!\!I}`X \,.\, y' = \max_P`\mathrm{C\!\!\!I}`X'.$$

If $x = \mu_P$ and $y = \nu_P$, put $x +_P y = (\mu +_c \nu)_P$. Then put X before X' if $(x +_P y) P (x' +_P y')$, or if $x +_P y = x' +_P y' \,.\, yPy'$. But if $x +_P y = x' +_P y'$ and $y = y'$, *i.e.* if $x = x' \,.\, y = y'$, take the immediate predecessors of x, y, x', y' in $\mathrm{D}`X$, $\mathrm{C\!\!\!I}`X$, $\mathrm{D}`X'$, $\mathrm{C\!\!\!I}`X'$ respectively, and apply the same tests to them, and so on, until we come to a difference. In this way, we obtain an arrangement by last differences (in a slightly extended sense), and this arrangement is easily shown to be an ω. Hence $\mu \epsilon \aleph_0$. Hence the class

$$\nu = \hat{\gamma}\{(\exists X) \,.\, X \epsilon \mu \,.\, \gamma = X \cup (\iota`B`P) \uparrow \overleftarrow{P}`\max_P`\mathrm{C\!\!\!I}`X\}$$

is an $\aleph_0$, and we have already shown that it is a median class of $C`P^P$. Hence

$$\vdash : P \epsilon \omega \,.\, \supset \,.\, \exists ! \aleph_0 \cap \overrightarrow{\mathrm{med}}`(P^P).$$

The same class will be a median class of $P^P \not\mapsto Z$, if $Z \sim \epsilon C`P^P$. Hence

$$\vdash : P \epsilon \omega \,.\, Z \sim \epsilon C`P^P \,.\, \supset \,.\, \exists ! \aleph_0 \cap \overrightarrow{\mathrm{med}}`(P^P \not\mapsto Z).$$

Hence, by what was proved earlier,

$$\vdash : P \epsilon \omega \,.\, Z \sim \epsilon C`P^P \,.\, \supset \,.\, (P^P \not\mapsto Z) \epsilon \theta,$$

i.e. $\vdash \,.\, (\omega \exp_r \omega) \dot{+} \dot{1} = \theta.$

PART VI.

QUANTITY.

SUMMARY OF PART VI.

THE purpose of this Part is to explain the kinds of applications of numbers which may be called *measurement*. For this purpose, we have first to consider generalizations of number. The numbers dealt with hitherto have been only integers (cardinal or ordinal); accordingly, in Section A, we consider positive and negative integers, ratios, and real numbers. (Complex numbers are dealt with later, under geometry, because they do not form a one-dimensional series.)

In Section B, we deal with what may be called "kinds" of quantity: thus *e.g.* masses, spatial distances, velocities, each form one kind of quantity. We consider each kind of quantity as what may be called a "vector-family," *i.e.* a class of one-one relations all having the same converse domain, and all having their domain contained in their converse domain. In such a case as spatial distances, the applicability of this view is obvious; in such a case as masses, the view becomes applicable by considering *e.g.* one gramme as + one gramme, *i.e.* as the relation of a mass m to a mass m' when m exceeds m' by one gramme. What is commonly called simply one gramme will then be the mass which has the relation + one gramme to the zero of mass. The reasons for treating quantities as vectors will be explained in Section B. Various different kinds of vector-families will be considered, the object being to obtain families whose members are capable of measurement either by means of ratios or by means of real numbers.

Section C is concerned with measurement, *i.e.* with the discovery of ratios, or of the relations expressed by real numbers, between the members of a vector-family. A family of vectors is measurable if it contains a member T (the unit) such that any other member S has to T a relation which is either a ratio or a real number. It will be shown that certain sorts of vector-families are in this sense measurable, and that measurement so defined has the mathematical properties which we expect it to possess.

Section D deals with *cyclic* families of vectors, such as angles or elliptic straight lines. The theory of measurement as applied to such families presents peculiar features, owing to the fact that any number of complete revolutions may be added to a vector without altering it. Thus there is not a single ratio of two vectors, but many ratios, of which we select one as the *principal* ratio.

SECTION A.

GENERALIZATION OF NUMBER.

Summary of Section A.

In this section, we first define the series of positive and negative integers. If μ is a cardinal, the corresponding positive and negative integers are the relations $+_c \mu$ and $-_c \mu$, or rather $(+_c \mu) \upharpoonright (\text{NC induct} - \iota`\Lambda)$ and $(-_c \mu) \upharpoonright (\text{NC induct} - \iota`\Lambda)$. (It will be observed that a positive integer must not be confounded with the corresponding signless integer, for while the former is a relation, the latter is a class of classes.) We next proceed to numerically-defined powers of relations, *i.e.* to R^ν, where ν is an inductive cardinal. We have already defined R^2 and R^3, but for the definition of ratio it is important to define R^ν generally. If $R \in 1 \to 1 \,.\, R_{po} \subset J$, we shall have $R^\nu = R_\nu$, and if $R \in \text{Ser}$, we shall have $(R_1)^\nu = R_\nu$. But these equations do not hold in general, and in particular if $R \subset I$ and $\nu \neq 0$, $R^\nu = R$ but $R_\nu = \dot{\Lambda}$. After a number devoted to relative primes, we proceed to the definition of signless ratios, thence to the multiplication and addition of signless ratios, thence to negative ratios, and thence to the generalized addition and multiplication which includes negative ratios. (In the case of ratios, signless ratios are identical with positive ratios. This is possible because signless ratios, unlike signless integers, are already relations.) We then proceed to the definition of real numbers, positive and negative, and to the addition and multiplication of real numbers. At each stage, we prove the commutative, associative, and distributive laws, and whatever else may seem necessary, for the particular kind of addition and multiplication in question.

Great difficulties are caused, in this section, by the existence-theorems and the question of types. These difficulties disappear if the axiom of infinity is assumed, but it seems improper to make the theory of (say) 2/3 depend upon the assumption that the number of objects in the universe is not finite. We have, accordingly, taken pains not to make this assumption, except where, as in the theory of real numbers, it is really essential, and not merely convenient. When the axiom of infinity is required, it is always explicitly stated in the hypothesis, so that our propositions, as enunciated, are true even if the axiom of infinity is false.

$*300$. POSITIVE AND NEGATIVE INTEGERS, AND NUMERICAL RELATIONS.

Summary of $*300$.

In this number, we introduce three definitions. We first define "U" as meaning the relation which holds between $\mu +_c \nu$ and μ whenever μ and ν are existent inductive cardinals of the same type, and $\nu \neq 0$, and $\mu +_c \nu$ exists in this type. Thus U is the relation "greater than" confined to existent inductive cardinals of the same type. The definition is:

$*300{\cdot}01$. $U = (+_c 1)_{po} \upharpoonright (\text{NC induct} - \iota`\Lambda)$ Df

Then if μ is an inductive cardinal which exists in the type in question, U_μ and $\breve{U}_\mu$ are the corresponding positive and negative integers, where "U_μ" has the meaning defined in $*121$. It will be observed that $0 U_\mu \mu$, so that U_μ exists, when μ exists in the type in question. We prove ($*300{\cdot}15$) that U is a series, and ($*300{\cdot}14$) that its field consists of all existent inductive cardinals of the type in question, its domain consists of all its field except 0, and its converse domain of all its field except the greatest (if any). If the axiom of infinity holds, $C`U$ consists of all inductive cardinals.

It will be observed that U arranges the inductive cardinals in *descending* order of magnitude. The reason for choosing this order instead of the converse is that U is less required in its serial use than as leading to the functional relations U_μ. As explained at the end of Part I, Section D, there is a broad difference between functional and serial relations, and this produces, where one relation (or its derivatives) is to have both uses, a certain conflict of convenience as to the *sense* in which the relation is to be taken. Considered as arranging the integers in a series, U would naturally be defined so as to arrange them in *ascending* order of magnitude, as was done with "N" in $*123$. But considered as functional relations, it is more convenient and more natural to take (say) $+_c 1$ as the relation to start with, and $-_c 1$ as its converse. Thus we want $\mu U_1 \nu$ when $\mu = \nu +_c 1$, *i.e.* we want $U_1`\nu = \nu +_c 1$; and this requires the definition of U given above.

We prove in this number ($*300{\cdot}23$) that $\breve{U}$ is well-ordered, and ($*300{\cdot}21{\cdot}22$) is either finite or a progression. We also prove ($*300{\cdot}17{\cdot}18$) that, if μ is any

typically indefinite inductive cardinal, μ and $\mu +_c 1$ will belong to $C'U$ if U is taken in a sufficiently high type.

Our other two definitions in this number define two classes of relations which are of vital importance in the theory of ratio. We define *numerical relations*, which are called "Rel num," as one-one relations whose powers are all contained in diversity, *i.e.* we put

∗300·02. $\text{Rel num} = (1 \to 1) \cap \hat{R}(\text{Pot}`R \subset \text{Rl}`J)$ Df

We thus have (∗300·3)

$$\vdash : R \in \text{Rel num} . \equiv . R \in 1 \to 1 . R_{po} \subseteq J.$$

It will be remembered that the hypothesis $R \in (\text{Cls} \to 1) \cup (1 \to \text{Cls}) . R_{po} \subseteq J$ played a great part in ∗121, and in all later work which depended upon ∗121. When both R and $\breve{R}$ fulfil this hypothesis, we have $R \in \text{Rel num}$, and vice versa. We prove (∗300·44) that if σ is an inductive cardinal not zero, and P is a series, then P_σ is a numerical relation, and so is $\breve{P}_\sigma$. If P is an endless well-ordered series, finid$`\breve{P}$ (*i.e.* the class of relations $\breve{P}_\sigma$) is what (in Section B) we shall call a vector-family: $\breve{P}_\sigma$ is the vector which carries a term σ steps along the series.

In order to be able to deal with zero, we have to consider the application of ratios, not only to such relations as are numerical in the above sense, but also to relations contained in identity, because a relation contained in identity may be regarded as a zero vector, so that (*e.g.*) if P is a series, $I \upharpoonright C`P$ will have a zero ratio to P_σ if σ is an inductive cardinal other than 0.

We therefore introduce a class "Rel num id" consisting of numerical relations together with such as are contained in identity: these may be called *numerical or identical relations*. They may be defined as one-one relations whose powers, other than R_0, are contained in diversity, because, if $R \subseteq I$, there are no powers other than R_0. Thus we put

∗300·03. $\text{Rel num id} = (1 \to 1) \cap \hat{R}(\text{Potid}`R - \iota`R_0 \subset \text{Rl}`J)$ Df

and we then prove

∗300·33. $\vdash . \text{Rel num id} = \text{Rl}`I \cup \text{Rel num}$

For the application of ratio, it is important to know under what circumstances there exists a numerical relation R such that R_σ is not null. We prove (∗300·45) that if σ is an inductive cardinal, and P is a series of $\sigma +_c 1$ terms, then $(B`P) P_\sigma (B`\breve{P})$. Now we also prove (∗300·44) that if P is a series, and $R = P_1$, $P_\sigma = R_\sigma$ and R is a numerical relation. Hence it follows, by ∗262·211, that if $\sigma \neq 0$ and α is a class of $\sigma +_c 1$ terms, there is

a numerical relation R whose field is of the same type as α and for which R_σ exists. Remembering *300·14 (quoted above), this proposition is:

***300·46.** $\vdash : \sigma \in \text{G}'U - \iota'0 \,.\supset.$

$(\exists P, R) \,.\, P \in (\sigma +_c 1)_r \,.\, R = P_1 \,.\, R \in \text{Rel num} \,.\, t'C'R = t_0'\sigma \,.\, (B'R) \, R_\sigma \, (B'\breve{R})$

We have conversely (*300·47)

$\vdash : R \in \text{Rel num} \,.\, \dot{\exists} \,!\, R_\sigma \,.\supset.\, \sigma \in \text{NC ind} \,.\, \exists \,!\, (\sigma +_c 1) \cap t'C'R \,.\, \sigma \cap t'C'R \in \text{G}'U,$

where "NC ind" has the meaning defined in *126, *i.e.* "$\sigma \in$ NC ind" means that σ is a typically indefinite cardinal.

The number ends by propositions proving (*300·52) that U_μ is a numerical relation, that (*300·57)

$$\dot{\exists} \,!\, (U_\xi)_\nu \,\dot{\cap}\, (U_\eta)_\mu \,.\supset.\, \xi \times_c \nu \in C'U \,.\, \xi \times_c \nu = \eta \times_c \mu,$$

and analogous theorems.

Summary of *301.

In this number, we have to exhibit the powers of a relation R, *i.e.* the various members of Potid$`R$, as of the form R^σ, where σ is an inductive cardinal. We have already had $R^2 = R \mid R$ and $R^3 = R^2 \mid R$. What we need is a definition which shall give

$$R^{\sigma +_c 1} = R^\sigma \mid R.$$

Now R^σ is a function of R and σ; thus we have to exhibit R^σ in the form $S`\sigma$, where S will be a function of R. That is, we have to define the relation S as a relation of R^σ to σ, and S must be such that, if it holds between R^σ and σ, it holds between $R^{\sigma +_c 1}$ and $\sigma +_c 1$. Thus we may take S as a sum of couples, such that if one couple is $R^\sigma \downarrow \sigma$, the next is $(R^\sigma \mid R) \downarrow (\sigma +_c 1)$, *i.e.* such that, if one couple is $Q \downarrow \sigma$, the next is $(Q \mid R) \downarrow (\sigma +_c 1)$. Now

$$(Q \mid R) \downarrow (\sigma +_c 1) = \{(\mid R) \parallel (-_c 1)\}`(Q \downarrow \sigma).$$

Hence, since we want to have $R^0 = I \upharpoonright C`R$, our class of couples is

$$\hat{M}\,[M\,\{(\mid R) \parallel (-_c 1)\}_* \,\{(I \upharpoonright C`R) \downarrow 0\}].$$

Calling this class num (R), we may therefore put

$$R^\sigma = \{\dot{s}`\text{num}\,(R)\}`\sigma \quad \text{Df.}$$

If we put $(\mid R) \parallel (-_c 1) = R_p$, the above definitions are

$$\text{num}\,(R) = \overrightarrow{(R_p)_*}`\{(I \upharpoonright C`R) \downarrow 0\} \quad \text{Dft},$$

$$R^\sigma = \{\dot{s}`\text{num}\,(R)\}`\sigma \qquad \text{Df.}$$

But the above definition of R_p requires some modification before it can be considered quite correct. With the above definition, we have

$$R_p`(Q \downarrow \sigma) = (Q \mid R) \downarrow (\sigma +_c 1) \qquad (1).$$

Now since num (R) is defined by means of $(R_p)_*$, and since the definition of R_* contains the hypothesis $\breve{R}``\mu \subset \mu$, it follows that, if num (R) is to be significant, the relation $-_c 1$ which appears in the definition of R_p must be homogeneous, so that, in (1), σ and $\sigma +_c 1$ must be of the same type. Hence σ, though typically ambiguous, cannot be typically indefinite;

therefore, if the axiom of infinity is not true, we shall sooner or later arrive at $\sigma = \Lambda$ as we travel up the inductive cardinals. In that case, we shall have

$$R^{\sigma -_c 1} \downarrow (\sigma -_c 1) \epsilon \operatorname{num}(R) . (R^{\sigma -_c 1} | R) \downarrow \Lambda \epsilon \operatorname{num}(R),$$
$$(R^{\sigma -_c 1} | R | R) \downarrow \Lambda \epsilon \operatorname{num}(R), \text{ etc.}$$

Now if (for example) R is a cyclic relation, such as that of an angle of a polygon to the next angle to the left, we shall not have

$$R^{\sigma -_c 1} = R^{\sigma -_c 1} | R \text{ or } R^{\sigma -_c 1} | R = R^{\sigma -_c 1} | R | R.$$

Hence $\dot{s}$'num (R) will fail to be one-many, and R^σ will fail to exist. Hence it becomes desirable to restrict σ to cardinals which exist in some assigned type, *i.e.* to replace $-_c 1$ by $(-_c 1) \upharpoonright$ (NC induct $- \iota$'Λ), *i.e.* by $\breve{U}_1$.

Thus we now put $\qquad R_p = (|R) \| \breve{U}_1$ Dft.

But even this definition is not quite complete, because the type of U is not assigned. It makes some difference how the type of U is assigned, for if we take as the type of C'U a type lower than that of t'N_0c't'R, we may find that our numbers become Λ before we have ceased to obtain fresh powers of R.

For example, suppose the total number of individuals were four, and that these were a, x, y, z. Let us write $x \downarrow (a, y, \ldots)$ for $x \downarrow a \cup x \downarrow y \cup \ldots$. Then consider the relation $R = x \downarrow (a, y) \cup a \downarrow y \cup y \downarrow (x, z)$. Then

$$R^2 = x \downarrow (x, y, z) \cup a \downarrow (x, z) \cup y \downarrow (a, y),$$
$$R^3 = x \downarrow (a, y, x, z) \cup a \downarrow (a, y) \cup y \downarrow (x, y, z),$$
$$R^4 = x \downarrow (y, x, z, a) \cup a \downarrow (y, x, z) \cup y \downarrow (a, y, x, z),$$
$$R^5 = x \downarrow (a, x, y, z) \cup a \downarrow (a, x, y, z) \cup y \downarrow (a, x, y, z).$$

After this, $R^6 = R^5 | R = R^5 | R^2 =$ etc. But up to R^5, each power of R is different from all its predecessors. If we take t'C'$U = t$'N_0c't'C'R, C'U consists only of the numbers 0, 1, 2, 3, 4, and is thus inadequate to deal with R^5. Hence the type in which we take U must be a sufficiently high type, which must increase with the type of R. Hence we take C'U in the type of t'N_0c't'R, *i.e.* in the type of t^3'R. This is secured by writing $U \upharpoonright t^3$'R in place of U in the definition of R_p. Hence the final definitions for R^σ are:

***301·01.** $R_p = (|R) \| (\breve{U}_1 \upharpoonright t^3\text{'}R)$ Dft [*301]

***301·02.** $\operatorname{num}(R) = \overrightarrow{(R_p)_*}\text{'}\{(I \upharpoonright C\text{'}R) \downarrow (0 \cap t^2\text{'}R)\}$ Dft [*301]

***301·03.** $R^\sigma = \{\dot{s}\text{'}\operatorname{num}(R)\}\text{'}\sigma$ Df

The two temporary definitions *301·01·02 are only to extend to the present number.

With the above definitions we have

***301·16.** $\vdash : \mu \,\epsilon\, C`U \cap t^3`R \,.\equiv.\, E\,!\,R^\mu$

***301·2.** $\vdash . R^0 = I \upharpoonright C`R \,.\, R^1 = R$

***301·21.** $\vdash : \nu \,\epsilon\, \text{Ɑ}`U \cap t^3`R \,.\supset.\, R^{\nu +_c 1} = R^\nu \,|\, R$

***301·23.** $\vdash : \mu +_0 \nu \,\epsilon\, C`U \cap t^3`R \,.\supset.\, R^{\mu +_c \nu} = R^\mu \,|\, R^\nu = R^\nu \,|\, R^\mu$

***301·26.** $\vdash : P \,\epsilon\, \text{Potid}`R \,.\equiv.\, (\exists\sigma) \,.\, P = R^\sigma$

I.e. the powers of R are the various relations R^σ. This proposition might have been not universally true if we had taken U in a lower type.

***301·3.** $\vdash : R \,\mathsf{G}\, I \,.\, \sigma \,\epsilon\, C`U \cap t^3`R \,.\supset.\, R^\sigma = R = R_0 = I \upharpoonright C`R$

It is largely for the sake of this proposition that we require powers of relations in dealing with ratio, rather than finid$`R$. For we have $R \,\mathsf{G}\, I \,.\, \sigma \neq 0 \,.\supset.\, R_\sigma = \dot{\Lambda}$, so that $R_\sigma$ does not give what is wanted if $R \,\mathsf{G}\, I$. On the other hand (\*301·41), if $R \,\epsilon\, \text{Rel num}$, we have $R^\sigma = R_\sigma$ if $\sigma \,\epsilon\, C`U \cap t^3`R$. Thus as applied to numerical relations, R_σ may always replace R^σ.

We have, whatever R may be,

***301·504.** $\vdash : \mu, \nu \,\epsilon\, C`U \cap t^2`C`R \,.\, \nu \neq 0 \,.\supset.\, (R^\mu)^\nu = R^{\mu \times_c \nu}$

The importance of this number will appear in connection with ratios.

$*302$. ON RELATIVE PRIMES.

Summary of $*302$.

The present number is merely preparatory for the definition and discussion of ratios. We want, of course, to give a definition of ratio which shall ensure that $\mu/\nu = (\mu \times_c \tau)/(\nu \times_c \tau)$. Hence in defining μ/ν in any given type, we cannot exact that μ and ν themselves should exist in that type, but only that, if ρ/σ is the same ratio in its lowest terms, ρ and σ should exist in that type. Hence, if we are not to assume the axiom of infinity, it is necessary to deal with relative primes before defining ratios.

The theory of relative primes is concerned with typically indefinite inductive cardinals (NC ind). It will be observed that we have three different sorts of inductive cardinals, namely NC ind, NC induct, and $C'U$. NC ind consists of typically indefinite cardinals, NC induct consists of all cardinals of some one type, and $C'U$ consists of all *existent* cardinals of some one type. If the axiom of infinity holds, we have $C'U = \text{NC induct}$, and $\text{NC ind} = \text{sm}``\text{NC induct}$. But neither of these is true if the axiom of infinity does not hold. It will be found that, where we require typically definite cardinals, it is $C'U$ or $\text{Cl}'U$ or $\text{D}'U$ that we require, not NC induct; that is to say, we almost always want to exclude Λ, and sometimes we want to exclude the greatest existent cardinal of the type in question, or to exclude 0. Thus "NC induct" will seldom occur in what follows. The cases in which $C'U$ or $\text{D}'U$ or $\text{Cl}'U$ occurs are of two sorts: (1) where we are proving typically definite existent-theorems, (2) where we are concerned with *series*, as *e.g.* in $*300$, where we considered the series of existent cardinals, or in $*304$ below, where we shall consider the series of ratios. Wherever *series* are concerned, we must have typical definiteness, because the definition of "$P \epsilon \text{Ser}$" involves $C'P$, and therefore only a *homogeneous* relation can be serial. This is a particular instance of the fact that when we require numbers as apparent variables (as *e.g.* in the theory of real numbers), typical definiteness becomes essential. Many propositions containing the hypothesis "$\mu \epsilon \text{NC ind}$" (where μ is a real variable) do not allow of μ being turned into an apparent variable, because this requires that μ should be fixed in one type, and our original proposition may demand that the

type in which μ is fixed should be a function of μ. For example, $*300\cdot17$ states

$$\vdash : \mu \epsilon \text{NC ind} . \supset . (\exists \alpha) . \mu \epsilon C'(U \upharpoonright t^{2'}\alpha).$$

If we fix the type of μ, we thereby also fix the type of α, and the proposition becomes false unless the axiom of infinity is true. In fact, the proposition demands that, the greater μ becomes, the higher must the type of α become. "NC ind" is not a strictly correct idea, and the primitive proposition $*9\cdot13$ does not apply without reserve to propositions in which it occurs. We have introduced it because it immensely simplifies the expression of many propositions, and because it is easy to avoid the errors to which it might give rise if used without remembering that it is a concession to convenience.

It will be found that, when we are not concerned with existence-theorems, or with numbers as apparent variables, "NC ind" is almost always the notion required. This applies to all cases where we are only concerned with addition, multiplication, subtraction and division; it applies to ratios except when ratios are considered as forming a series, or when we are investigating their existence. As regards the use of an "NC ind" as an apparent variable, there is a distinction between "all values" and "some value." If we have "$\rho \epsilon \text{NC ind}$," "$(\exists \rho)$" will often be legitimate when "(ρ)" is not. The reason of this is that, if we are to fix upon one typically indefinite cardinal, it will be possible to assign one definite type in which it exists; *e.g.* there are at least two classes four classes of classes, sixteen classes of classes of classes, and so on. But if we are making a statement about *all* typically indefinite inductive cardinals, it will not be true unless there is a type such that our statement holds of all inductive cardinals in this type.

In virtue of $*300\cdot17$, if we have "$\rho \epsilon \text{NC ind}$," we may replace it by "$\rho \epsilon C'U$" if we may take U in as high a type as we please, or if, on account of the rest of our proposition, ρ cannot be greater than some assigned inductive cardinal so long as the hypothesis of our proposition is true.

The above remarks will enable the reader to test the uses of typically indefinite inductive cardinals as apparent variables, and the passage from propositions concerning NC ind to propositions concerning $C'U$.

We define ρ as prime to σ when both are typically indefinite cardinals and 1 is their only common factor, *i.e.* we put

$*302\cdot01$. $\text{Prm} = \hat{\rho}\hat{\sigma} \{\rho, \sigma \epsilon \text{NC ind} : \rho = \xi \times_0 \tau . \sigma = \eta \times_0 \tau . \supset_{\xi, \eta, \tau} . \tau = 1\}$ Df

In this definition, ξ, η, τ may be taken to be typically indefinite cardinals; because, when $\rho = \xi \times_0 \tau . \sigma = \eta \times_0 \tau$, we must have $\xi \leqslant \rho . \eta \leqslant \sigma . \tau \leqslant \rho . \tau \leqslant \sigma$, so that ξ, η, τ cannot grow indefinitely (with a given ρ and σ) while the hypothesis remains true.

We define "$(\rho, \sigma) \text{Prm}_\tau (\mu, \nu)$" as meaning that ρ is prime to σ, that τ is not zero, and $\mu = \rho \times_0 \tau . \nu = \sigma \times_0 \tau$, *i.e.* ρ/σ is μ/ν in its lowest terms, and τ is the highest common factor of μ and ν. The definition is:

***302·02.** $(\rho, \sigma) \operatorname{Prm}_\tau (\mu, \nu) . = .$

$$\rho \operatorname{Prm} \sigma . \tau \in \mathrm{NC\,ind} - \iota`0 . \mu = \rho \times_c \tau . \nu = \sigma \times_c \tau \quad \mathrm{Df}$$

We then put further

***302·03.** $(\rho, \sigma) \operatorname{Prm} (\mu, \nu) . = . (\exists \tau) . (\rho, \sigma) \operatorname{Prm}_\tau (\mu, \nu) \quad \mathrm{Df}$

Here again there is no objection to τ as an apparent variable, because τ must be not greater than μ and ν. "$(\rho, \sigma) \operatorname{Prm} (\mu, \nu)$" secures that ρ/σ is μ/ν in its lowest terms.

We also define, in this number, the lowest common multiple and the highest common factor.

Our definition of "Prm" is so framed that every inductive cardinal is prime to 1 (*302·12), that 1 is the only number which is prime to itself (*302·13), and the only number which is prime to 0 (*302·14).

After a number of preliminary propositions, we arrive at the result that if μ and ν are not both zero, and ξ and η are not both zero, the existence of a couple ρ, σ which is prime both to μ, ν and to ξ, η is equivalent to $\mu \times_c \eta = \nu \times_c \xi$, *i.e.*

***302·34.** $\vdash :. \mu, \nu, \xi, \eta \in \mathrm{NC\,ind} . \sim(\mu = \nu = 0) . \sim(\xi = \eta = 0) . \supset :$

$$\mu \times_c \eta = \nu \times_c \xi . \equiv . (\exists \rho, \sigma) . (\rho, \sigma) \operatorname{Prm} (\mu, \nu) . (\rho, \sigma) \operatorname{Prm} (\xi, \eta)$$

We have also

***302·36.** $\vdash : \mu, \nu \in \mathrm{NC\,ind} . \sim(\mu = \nu = 0) . \equiv . (\exists \rho, \sigma) . (\rho, \sigma) \operatorname{Prm} (\mu, \nu)$

***302·38.** $\vdash : (\rho, \sigma) \operatorname{Prm} (\mu, \nu) . (\xi, \eta) \operatorname{Prm} (\mu, \nu) . \supset . \rho = \xi . \sigma = \eta$

I.e. there is only one way of reducing a fraction to its lowest terms.

We prove also (*302·15) that if μ, ν are typically indefinite cardinals, which both exist in the type of λ (*i.e.* $\mu_\lambda, \nu_\lambda \in C`U$), then

$$(\rho, \sigma) \operatorname{Prm} (\mu, \nu) . \equiv . (\rho, \sigma) \operatorname{Prm} (\mu_\lambda, \nu_\lambda).$$

This enables us, when we wish, to substitute typically definite cardinals for the typically indefinite μ and ν.

***302·01.** $\operatorname{Prm} = \hat{\rho}\hat{\sigma} \{\rho, \sigma \in \mathrm{NC\,ind} : \rho = \xi \times_c \tau . \sigma = \eta \times_c \tau . \supset_{\xi, \eta, \tau} . \tau = 1\} \quad \mathrm{Df}$

***302·02.** $(\rho, \sigma) \operatorname{Prm}_\tau (\mu, \nu) . = .$

$$\rho \operatorname{Prm} \sigma . \tau \in \mathrm{NC\,ind} - \iota`0 . \mu = \rho \times_c \tau . \nu = \sigma \times_c \tau \quad \mathrm{Df}$$

Here μ, ν are to be typically indefinite in the same way as $\rho \times_c \tau$ and $\sigma \times_c \tau$. Thus if, in some one type, $\rho \times_c \tau$ and $\sigma \times_c \tau$ are both null, that does not justify us in writing $(\rho, \sigma) \operatorname{Prm}_\tau (\Lambda, \Lambda)$, because there are other types in which $\rho \times_c \tau$ and $\sigma \times_c \tau$ are not null. On this subject, cf. *126.

***302·03.** $(\rho, \sigma) \operatorname{Prm} (\mu, \nu) . = . (\exists \tau) . (\rho, \sigma) \operatorname{Prm}_\tau (\mu, \nu) \quad \mathrm{Df}$

*303. RATIOS.

Summary of *303.

In this number, we give the definition and elementary properties of the ratio μ/ν. Most of the important applications of ratios are to numerical or identical relations, *i.e.* to relations which may, in a certain sense, be called *vectors*. Neglecting identical relations for the moment, let us consider numerical relations, and to fix our ideas, let us take distances on a line. A distance on a line is a one-one relation whose converse domain (and its domain too) is the whole line. If we call two such distances R and S, we may say that they have the ratio μ/ν if, starting from some point x, ν repetitions of R take us to the same point y as we reach by μ repetitions of S, *i.e.* if $xR^\nu y \,.\, xS^\mu y$. Thus R and S will have the ratio μ/ν if $\dot{\exists} ! R^\nu \dot{\cap} S^\mu$. In order, however, to insure that $\mu/\nu = \rho/\sigma$ if $(\rho, \sigma) \operatorname{Prm} (\mu, \nu)$, it is necessary, in general, to substitute $\dot{\exists} ! R^\sigma \dot{\cap} S^\rho$ for $\dot{\exists} ! R^\nu \dot{\cap} S^\mu$. (In the above case of distances on a line, the two are equivalent.) Thus we shall say that R has the ratio μ/ν to S if $(\exists \rho, \sigma) \,.\, (\rho, \sigma) \operatorname{Prm} (\mu, \nu) \,.\, \dot{\exists} ! R^\sigma \dot{\cap} S^\rho$.

If we apply the above definition to identical relations, we find that, if $R \mathrel{\dot{\subset}} I \,.\, S \mathrel{\dot{\subset}} I$, R has the ratio μ/ν to S provided $\dot{\exists} ! R \dot{\cap} S$, *i.e.* provided $\exists ! C\text{‘}R \cap C\text{‘}S$. This application is required for dealing with zero quantities and zero ratios.

Thus we are led to the following definition of ratios:

***303·01.** $\mu/\nu = \hat{R}\hat{S} \{(\exists \rho, \sigma) \,.\, (\rho, \sigma) \operatorname{Prm} (\mu, \nu) \,.\, \dot{\exists} ! R^\sigma \dot{\cap} S^\rho\}$ Df

This definition, as it stands, requires justification in two respects: (1) we commonly think of ratios as applying to magnitudes other than relations, (2) we should not commonly include as examples of ratio certain cases included in the above definition. These two points must now be considered.

(1) In applying our theory to (say) the ratio of two masses, we note that the idea of quantity (say, of mass) in any usage depends upon a comparison of different quantities. The "vector quantity" R, which relates a quantity m_1 with a quantity m_2, is the relation arising from the existence of some definite physical process of addition by which a body of mass m_1 will be transformed into another body of mass m_2. Thus σ such steps, symbolized by R^σ,

represents the addition of the mass $\sigma(m_2 - m_1)$. Similarly if S is the relation between M_2 and M_1 which arises from the process of addition turning a body of mass M_1 into another body of mass M_2, then S^ρ symbolizes the addition of the mass $\rho(M_2 - M_1)$. Now $\exists ! R^\sigma \dot{\cap} S^\rho$ means that there are a pair of masses m and m', such that $mR^\sigma m'$ and $mS^\rho m'$. In other words, if we take a body A of mass m and transform it so as to turn it into another of mass $m + \sigma(m_2 - m_1)$, we obtain a body of the same mass m' as if we proceeded to transform A into a body of mass $m + \rho(M_2 - M_1)$. Hence $\sigma(m_2 - m_1) = \rho(M_2 - M_1)$; that is $(m_2 - m_1)/(M_2 - M_1) = \rho/\sigma$. But in our symbolism the addition of $m_2 - m_1$ is represented by the vector quantity R, and that of $M_2 - M_1$ by the vector quantity S; so in our symbolism R has to S the ratio of ρ to σ.

Thus to say that an entity possesses μ units of quantity means that, taking U to represent the unit vector quantity, U^μ relates the zero of quantity—whatever that may mean in reference to that kind of quantity—with the quantity possessed by that entity.

It can be claimed for this method of symbolizing the ideas of quantity (α) that it is always a possible method of procedure whatever view be taken of it as a representation of first principles, and (β) that it directly represents the principle "No *quantity* of any kind without a comparison of different quantities of that kind."

Furthermore analogously to our treatment of cardinal and ordinal numbers, we can define any definite quantity of some kind, say any definite quantity of mass, as being merely the class of all "bodies of equal mass" with some given body. The zero mass will be the class of all bodies of zero mass; and if there are no bodies with the properties that a body of zero mass should have, this class reduces to Λ in the appropriate type.

Thus the application of our symbolism to concrete cases demands the existence of a determinate test of "equality of quantity" of different entities, and a determinate process of "addition of quantity." The formal properties which the process of addition must possess are discussed in the numbers concerned with vector families.

(2) Having now shown that cases apparently excluded by our definition of ratio can be included, we have to show that no harm is done by our inclusion of cases which would naturally be excluded. In order that ratio may agree with our expectations it is necessary that the two relations R and S, whose ratio we are considering, should have the same converse domain. Otherwise we get such cases as the following: Let P, Q be two series, and suppose* $B'P = B'Q$, $5_P = 6_Q$, $11_P = 9_Q$, $13_P = 25_Q$, but that P and Q have no other terms in common. Then we shall have, if $R = P_1 . S = Q_1$,

$$(B'P)\, R^4\, 5_P \,.\, (B'P)\, S^5\, 5_P,$$

* For notation, cf. *121.

whence it follows that R has to S the ratio 5/4, *i.e.* we have $R(5/4)S$. But we shall also have $R(8/10)S$ and $R(24/12)S$, *i.e.* $R(4/5)S$ and $R(2/1)S$. Thus our definition does not make different ratios incompatible. In practical applications, however, when R and S are confined to one vector-family, different ratios do become incompatible, as will be proved at the beginning of Section C. And so long as we are not concerned with the applications which constitute measurement, the important thing about our definition of ratio is that it should yield the usual arithmetical properties, in particular the fundamental property

$$\mu/\nu = \rho/\sigma \,.\equiv.\, \mu \times_0 \sigma = \nu \dot{\times}_0 \rho,$$

which is proved, with our definition, in *303·39. Thus any further restriction in the definition would constitute an unnecessary complication.

In virtue of our definition of μ/ν, $\mu/\nu = \dot{\Lambda}$ if μ and ν are not both inductive cardinals, or if $\mu = \nu = 0$ (*303·11·14). We have (*303·13) $\vdash . \mu/\nu = \mathrm{Cnv}`(\nu/\mu)$, *i.e.* the converse of a ratio is its reciprocal. If $\mu = 0$, and $R(\mu/\nu)S$, R must have a part in common with identity (which we may express by saying that R is a zero vector), and S may be any numerical or identical relation whose field has a member which has the relation R to itself (*303·15). Thus if ν, σ are inductive cardinals other than 0, $0/\nu = 0/\sigma$. The common value of ratios whose numerator is 0 is the zero ratio, which we call 0_q (where "q" is intended to suggest "quantity"). The definition of 0_q is

***303·02.** $0_q = \dot{s}`0/``\mathrm{NC\,induct}$ Df

In like manner, if μ and ρ are inductive cardinals other than 0, we have $\mu/0 = \rho/0$. The common value of such ratios we call ∞_q, putting

***303·03.** $\infty_q = \dot{s}`/0``\mathrm{NC\,induct}$ Df

The properties of ratios require various existence-theorems, and in establishing existence-theorems without assuming the axiom of infinity, the question of types requires considerable care. We have

***303·211.** $\vdash : (\rho, \sigma)\,\mathrm{Prm}\,(\mu, \nu) \,.\supset.\, \mu/\nu = \rho/\sigma$

so that the existence of μ/ν does not depend upon μ and ν, but upon ρ and σ, where ρ/σ is μ/ν in its lowest terms. We may, therefore, in considering existence-theorems, confine ourselves, in the first instance, to *prime* ratios.

To prove the existence of $(\rho/\sigma) \upharpoonright t`R$, when $\rho\,\mathrm{Prm}\,\sigma$, we take two relations R and S both contained in identity. These have the ratio ρ/σ provided their fields have a member in common and $\mathrm{E}\,!\,R^\sigma . \mathrm{E}\,!\,S^\rho$. By *301·16, this requires $\rho, \sigma \in C``(U \upharpoonright t^{3}`R)$. Thus we have

***303·25.** $\vdash :. \rho\,\mathrm{Prm}\,\sigma \,.\supset:$

$$\dot{\exists}\,!\,(\rho/\sigma) \upharpoonright t`R \,.\equiv.\, \rho, \sigma \in C``(U \upharpoonright t^{3}`R) \,.\equiv.\, \rho(R), \dot{\sigma}(R) \in C`U$$

But this existence-theorem, which is obtained by supposing R and S contained in identity, is not much use in practice: what we require is the existence of a ratio between *numerical* relations. For this purpose, assuming $\rho \geqslant \sigma$ and $\sigma \neq 0$, let λ be a class of such a type that $\mathrm{Nc}'t'\lambda \geqslant \rho +_0 1$. (Such a class can always be found in some type, by $*300{\cdot}18$.) Then we have $\rho_\lambda \in \mathrm{G}'U$, and we can construct a series Q such that $C'Q$ is of the same type as λ and $\mathrm{Nc}'C'Q = \rho +_0 1$. (This is proved in $*262{\cdot}211$.) We can then choose out of Q a series P having the same beginning and end, and consisting of $\sigma +_0 1$ terms. We then have

$$(B'Q)(Q_1)^\rho(B'\breve{Q}) \,.\, (B'Q)(P_1)^\sigma(B'\breve{Q}).$$

Hence P_1 and Q_1 have the ratio ρ/σ. A similar argument applies if $\sigma \geqslant \rho$ and $\rho \neq 0$. Thus we arrive at the proposition:

$*303{\cdot}322.\ \vdash : \rho \,\mathrm{Prm}\, \sigma \,.\, \rho_\lambda, \sigma_\lambda \in \mathrm{D}'U \cap \mathrm{G}'U \,.\, \supset .\, \dot{\exists} ! (\rho/\sigma) \upharpoonright (\mathrm{Rel\,num} \cap t_{00}'\lambda)$

I.e. if ρ is prime to σ and neither is 0, and $\rho +_0 1$, $\sigma +_0 1$ both exist in the type of λ, then there are numerical relations having the ratio ρ/σ and having their fields of the same type as λ.

The case when either ρ or σ is 0 requires separate treatment. If R has to S the ratio $0/\sigma$, R must be partly contained in identity ($*303{\cdot}15$); hence we have to find a hypothesis for $\dot{\exists} ! (0/\sigma) \upharpoonright \mathrm{Rel\,num}$, since $\dot{\exists} ! (0/\sigma) \upharpoonright \mathrm{Rel\,num}$ is impossible. Since $0/\sigma = 0/1$, we only require the existence of 2 in the appropriate type, *i.e.* we have

$*303{\cdot}63.\ \vdash : \exists ! 2_\lambda \,.\, \supset .\, \dot{\exists} ! 0_q \upharpoonright (\mathrm{Rel\,num} \cap t_{00}'\lambda)$

It will be remembered that $\exists ! 2_\lambda$ is demonstrable except in the lowest type.

In the above propositions, μ and ν and ρ and σ have been typically indefinite. Ratios of typically definite inductive cardinals are dealt with by means of $*302{\cdot}15$, which gives at once

$*303{\cdot}27.\ \vdash : \mu, \nu \in \mathrm{NC\,ind} \,.\, \mu_\lambda, \nu_\lambda \in C'U \,.\, \supset .\, \mu/\nu = \mu_\lambda/\nu_\lambda$

I.e. a ratio may, without changing its value, have its numerator and denominator specified as belonging to any type in which both exist. This enables us to take ρ and σ as typically definite cardinals in $*303{\cdot}322$, thus obtaining the proposition

$*303{\cdot}332.\ \vdash :. \rho \,\mathrm{Prm}\, \sigma \,.\, \supset : \dot{\exists} ! (\rho/\sigma) \upharpoonright (\mathrm{Rel\,num} \cap t_{11}'\rho) \,.\, \equiv .\, \rho, \sigma \in \mathrm{D}'U \cap \mathrm{G}'U$

The above existence-theorems are useful in proving

$$\alpha/\beta = \gamma/\delta \,.\, \equiv .\, \alpha \times_0 \delta = \beta \times_0 \gamma.$$

We proceed as follows: We first show ($*303{\cdot}34$) that, if ρ, σ are inductive cardinals other than 0, and $\rho +_0 1$, $\sigma +_0 1$ exist in the type of λ, we can find numerical relations R and S such that $\dot{\exists} ! R^\sigma \dot{\cap} S^\rho$, but $\eta > \sigma \,.\, \supset .\, \sim\dot{\exists} ! R^\eta$.

This is done by taking two series P and Q having the same beginning and end, and having $C'P \epsilon \sigma +_0 1 . C'Q \epsilon \rho +_0 1$. Then if $R = P_1$ and $S = Q_1$, we have

$$(B'P) R^\sigma (B'\breve{P}) . (B'P) S^\rho (B'\breve{P}) : \eta > \sigma . \supset . R^\eta = \Lambda,$$

whence the result. From this proposition it follows immediately that if $\rho \operatorname{Prm} \sigma . \xi \operatorname{Prm} \eta . \eta > \sigma$, and if $\rho_\lambda, \sigma_\lambda \epsilon \mathrm{D}'U \cap \mathrm{Cl}'U$, we can find an R and an S such that $R (\rho/\sigma) S . \sim \{R (\xi/\eta) S\}$. A similar argument applies if $\eta < \sigma$ or $\xi > \rho$ or $\xi < \rho$. Hence we find, by transposition,

∗303·341. $\vdash : \rho_\lambda, \sigma_\lambda \epsilon \mathrm{D}'U \cap \mathrm{Cl}'U . \rho \operatorname{Prm} \sigma . \xi \operatorname{Prm} \eta . (\rho/\sigma) \upharpoonright t_{00}'\lambda = (\xi/\eta) \upharpoonright t_{00}'\lambda . \supset . \rho = \xi . \sigma = \eta$

From this point on, the argument offers no difficulty. For if we have

$$\alpha/\beta = \gamma/\delta . (\rho, \sigma) \operatorname{Prm} (\alpha, \beta) . (\xi, \eta) \operatorname{Prm} (\gamma, \delta),$$

we have, by ∗303·341·211, $\rho = \xi . \sigma = \eta$. Hence, by ∗302·32, we have $\alpha \times_0 \delta = \beta \times_0 \gamma$. What is approximately the converse, *i.e.*

∗303·23. $\vdash : \mu, \nu, \xi, \eta \epsilon \mathrm{NC} \operatorname{ind} .$
$\sim (\mu = \nu = 0) . \sim (\xi = \eta = 0) . \mu \times_0 \eta = \nu \times_0 \xi . \supset . \mu/\nu = \xi/\eta$

follows at once from ∗303·211 and ∗302·3. Hence, after dealing with special cases, we find

∗303·38. $\vdash :. \alpha, \beta, \gamma, \delta \epsilon \mathrm{NC} \operatorname{ind} :$
$\alpha_\lambda, \beta_\lambda \epsilon \mathrm{Cl}'U . \mathsf{v} . \gamma_\lambda, \delta_\lambda \epsilon \mathrm{Cl}'U : \sim (\alpha = \beta = 0) . \sim (\gamma = \delta = 0) : \supset :$
$(\alpha/\beta) \upharpoonright t_{00}'\lambda = (\gamma/\delta) \upharpoonright t_{00}'\lambda . \equiv . \alpha \times_0 \delta = \beta \times_0 \gamma$

It will be observed that α/β is typically indefinite, like $\mathrm{Nc}'\xi$. But in order to insure that $\alpha/\beta = \gamma/\delta$ however the type may be determined, it is only necessary to insure that this equation holds in a type in which $(\alpha/\beta) \upharpoonright \operatorname{Rel} \operatorname{num}$ exists. When we write simply "$\alpha/\beta = \gamma/\delta$," we shall mean that this equation holds however the type may be determined; in other words, that it holds in a type in which $(\alpha/\beta) \upharpoonright \operatorname{Rel} \operatorname{num}$ exists. (There always is such a type, if $\alpha, \beta \epsilon \mathrm{NC} \operatorname{ind} - \iota'0$, in virtue of ∗303·322 and ∗300·18.) Thus we have

∗303·391. $\vdash :. \alpha, \beta \epsilon \mathrm{NC} \operatorname{ind} . \alpha_\lambda, \beta_\lambda \epsilon \mathrm{Cl}'U . \sim (\alpha = \beta = 0) . \supset :$
$(\alpha/\beta) \upharpoonright t_{00}'\lambda = (\gamma/\delta) \upharpoonright t_{00}'\lambda . \equiv . \alpha/\beta = \gamma/\delta . \equiv . \alpha \times_0 \delta = \beta \times_c \gamma$

and, in virtue of ∗303·38, we have

∗303·39. $\vdash :. \alpha, \beta, \gamma, \delta \epsilon \mathrm{NC} \operatorname{ind} . \sim (\alpha = \beta = 0) . \sim (\gamma = \delta = 0) . \supset :$
$\alpha/\beta = \gamma/\delta . \equiv . \alpha \times_0 \delta = \beta \times_0 \gamma$

This proposition is, of course, essential to the justification of our definition of ratios.

The remaining propositions of ∗303 consist (1) of applications of the theory of ratio to powers of a given numerical relation, (2) of properties of 0_q and ∞_q, (3) of a few properties of the class of ratios. This last set of propositions depends upon two new definitions, which must be briefly explained.

We have already explained that μ/ν is typically indefinite. Thus if we call μ/ν a "ratio," ratios are, like "NC ind," not strictly a class, because every class must be confined within some one type. Nevertheless it is convenient, just as in the case of NC ind, to treat ratios as if they formed a class; and, with similar precautions, we can avoid the errors into which we might be led by treating them as a proper class. We therefore put

***303·04.** $\text{Rat} = \hat{X}\{(\exists\mu, \nu) . \mu, \nu \in \text{NC ind} . \nu \neq 0 . X = \mu/\nu\}$ Df

(The condition $\nu \neq 0$ is only introduced because it is usually convenient to exclude ∞_q.) It will be observed that μ/ν is still typically indefinite if μ and ν are typically definite. This results from *303·27. But we often want typically definite ratios. We want these defined in types in which there are numerical relations having the ratios in question. Hence we put

***303·05.** $\text{Rat def} = \hat{X}\{(\exists\mu, \nu) . \mu, \nu \in \text{D}`U \cap \text{G}`U . X = (\mu/\nu) \upharpoonright t_{11}`\mu\}$ Df

Here "def" stands for "definite," and μ, ν are typically definite inductive cardinals. The desired properties of "Rat def" result from *303·322. It should be observed that, besides consisting of typically definite ratios, "Rat def" differs from "Rat" by the exclusion of 0_q. This is merely for reasons of convenience.

The properties of "Rat" and "Rat def" follow immediately from previous propositions. We have

***303·721.** $\vdash : X \in \text{Rat} - \iota`0_q . \supset . (\exists\mu) . X \upharpoonright t_{11}`\mu \in \text{Rat def}$

***303·73.** $\vdash : X \in \text{Rat def} . \supset . \dot{\exists} ! X \upharpoonright \text{Rel num}$

By *303·322; and by *303·391,

***303·76.** $\vdash :. X, Y \in \text{Rat} . X \upharpoonright t_{11}`\rho \in \text{Rat def} . \supset : X \upharpoonright t_{11}`\rho = Y \upharpoonright t_{11}`\rho . \equiv . X = Y$

If the axiom of infinity holds, every member of "Rat" except 0_q becomes a member of "Rat def" as soon as it is made typically definite. Hence

***303·78.** $\vdash : \text{Infin ax} . \supset . \text{Rat def} = \text{Rat} - \iota`0_q$

The uses of "Rat" and "Rat def" differ just as the uses of "NC ind" and "NC induct" differ. The distinction is only important so long as the axiom of infinity is not assumed.

***303·01.** $\mu/\nu = \hat{R}\hat{S}\{(\exists\rho, \sigma) . (\rho, \sigma) \text{Prm} (\mu, \nu) . \dot{\exists} ! R^\sigma \dot{\cap} S^\rho\}$ Df

In the above definition, ρ, σ, μ, ν are typically ambiguous, but ρ, σ must (by *301·16) exist in the type of $t`R$, while μ, ν need not do so; μ, ν cannot however, be null in *all* types, by *300·17.

***303·02.** $0_q = \dot{s}`0/``\text{NC induct}$ Df

***303·03.** $\infty_q = \dot{s}`/0``\text{NC induct}$ Df

***303·04.** $\text{Rat} = \hat{X}\{(\exists \mu, \nu) . \mu, \nu \in \text{NC ind} . \nu \neq 0 . X = \mu/\nu\}$ Df

***303·05.** $\text{Rat def} = \hat{X}\{(\exists \mu, \nu) . \mu, \nu \in \text{D}`U \cap \text{G}`U . X = (\mu/\nu) \upharpoonright t_{11}`\mu\}$ Df

***303·1.** $\vdash : R(\mu/\nu) S . \equiv . (\exists \rho, \sigma) . (\rho, \sigma) \text{Prm} (\mu, \nu) . \dot{\exists} ! R^\sigma \dot{\cap} S^\rho$ [(*303·01)]

In the above proposition, if μ/ν is typically indefinite, so that "$\dot{\exists} !\, \mu/\nu$" only asserts existence in a sufficiently high type, ρ, σ may also be typically indefinite. But if μ/ν is to be taken in a definite type, ρ and σ must be taken in the corresponding type, and must not be null in that type. This is proved later.

***303·182.** $\vdash :. 0/0 = \mu/\nu \,.\equiv : \sim(\mu, \nu \in \mathrm{NC\,ind}) \,.\vee .\, \mu = \nu = 0$

Dem.

$\vdash . *64\cdot51\cdot55 . \supset \vdash : \mu = \mathrm{Nc}\text{‘}\alpha . \alpha \in t\text{‘}C\text{‘}R . x \in t_0\text{‘}C\text{‘}R . \supset . \downarrow x\text{‘‘}\alpha \in \mu \cap t^{2}\text{‘}R \qquad (1)$

$\vdash . (1) . *300\cdot14 . \supset \vdash : \mathrm{Hp} . \supset . \mu, \nu \in C\text{‘}U \upharpoonright t^{3}\text{‘}R \qquad (2)$

$\vdash . (2) . *303\cdot251 . \supset \vdash . \mathrm{Prop}$

In the above proof, μ, ν are assumed to be typically indefinite. If they are typically definite, $\mathrm{sm}\text{‘‘}\mu$ and $\mathrm{sm}\text{‘‘}\nu$ must be substituted for μ and ν on the right-hand side of (1) and (2). The hypothesis "$\mu, \nu \in \mathrm{NC\,ind} \cap C\text{‘}U \upharpoonright t^{2}\text{‘}C\text{‘}R$" is a convenient abbreviation for

"$\mu, \nu \in \mathrm{NC\,ind} . \mu \cap t\text{‘}C\text{‘}R, \nu \cap t\text{‘}C\text{‘}R \in C\text{‘}U \upharpoonright t^{2}\text{‘}C\text{‘}R .$"

By *65·13,

$$\mu \cap t\text{‘}C\text{‘}R \in C\text{‘}U \upharpoonright t^{2}\text{‘}C\text{‘}R . \equiv . \mu \subset t\text{‘}C\text{‘}R . \mu \in C\text{‘}U \upharpoonright t^{2}\text{‘}C\text{‘}R . \equiv . \mu \in C\text{‘}U \upharpoonright t^{2}\text{‘}C\text{‘}R.$$

But "$\mu \in C\text{‘}U \upharpoonright t^{2}\text{‘}C\text{‘}R$" requires that μ should be typically definite, whereas "$\mu \in \mathrm{NC\,ind}$" requires that μ should be typically indefinite. Hence the hypothesis of *303·252 is only defensible as an abbreviation, meaning "$\mu, \nu \in \mathrm{NC\,ind}$, and if μ, ν are given the suitable typical definition, they become members of $C\text{‘}U \upharpoonright t^{2}\text{‘}C\text{‘}R$."

The above two propositions assume that μ/ν in the first, and "Rat" in the second, have been made typically definite, but they hold however the type may be defined.

$*$304. THE SERIES OF RATIOS.

Summary of $*$304.

In this number we consider the relation of greater and less among ratios, and the series generated by this relation. We need two different notations, one for greater and less between typically indefinite ratios, the other for greater and less between ratios of the same type. The former is more useful where we are dealing merely with inequalities between specified ratios, but the latter is necessary when we wish to consider the *series* of ratios in order of magnitude, since a series must be composed of terms which are all of the same type. We put

$*$304·01. $X <_r Y . = . (\exists \mu, \nu, \rho, \sigma) . \mu, \nu, \rho, \sigma \in \mathrm{NC\,ind} . \sigma \neq 0 . \mu \times_c \sigma < \nu \times_c \rho .$
$X = \mu/\nu . Y = \rho/\sigma$ Df

This definition is so framed as to include 0_q but exclude ∞_q. For the relation "less than" among rationals of given type (excluding 0_q), we use the letter H, to suggest η (defined in $*$273), because, if the axiom of infinity holds, the series of rationals of a given type is an η. The definition is

$*$304·02. $H = \hat{X}\hat{Y}\{X, Y \in \mathrm{Rat\,def} . X <_r Y\}$ Df

When we wish to include 0_q in the series, we use the notation H'; thus

$*$304·03. $H' = \hat{X}\hat{Y}\{X, Y \in \mathrm{Rat\,def} \cup \iota`0_q . X <_r Y\}$ Df

(It will be observed that here $\iota`0_q$ acquires typical definiteness through the fact that it must be of the same type as "Rat def" in order to make "Rat def $\cup\, \iota`0_q$" significant.)

If the axiom of infinity does not hold, H and H' will be finite series: if $\nu +_c 1$ is the greatest integer in a given type ($\nu > 1$), the first term of H is $1/\nu$ and the last is $\nu/1$ ($*$304·281). In a higher type, we shall get a larger series for H, but at no stage shall we get an infinite series. If, on the other hand, the axiom of infinity does hold, H is a compact series ($*$304·3) without beginning or end ($*$304·31) and having $\aleph_0$ terms in its field ($*$304·32), *i.e.* H is an η ($*$304·33). In this case, $C`H = \mathrm{D}`H = \mathrm{Rat} - \iota`0_q$ ($*$304·34), *i.e.* any rational other than $0_q$, as soon as it is made typically definite, belongs to $C`H$.

Under all circumstances, H is a series (*304·23), and H exists in the type $t_{00}{}^{\backprime}\lambda$ if 3 exists in the type $t^{\backprime}\lambda$ (*304·27). In the same case, $C^{\backprime}H = \text{Rat def}$ (*304·28). Similar propositions hold for H'.

$C^{\backprime}H'$ consists of typically definite ratios, and if X is any ratio, there are types in which X belongs to $C^{\backprime}H'$ (*304·52). If the axiom of infinity holds, every ratio is a member of $C^{\backprime}H$ in every type (*304·49).

*305. MULTIPLICATION OF SIMPLE RATIOS.

Summary of *305.

The ratios hitherto considered are called "simple" ratios in opposition to "generalized" ratios (introduced in *307), which include negative ratios. We deal with multiplication and addition first for simple ratios, and then for generalized ratios. In this number we are only concerned with the multiplication of simple ratios.

In defining multiplication of ratios, we naturally frame our definition so as to secure that the product of μ/ν and ρ/σ shall be $(\mu \times_c \rho)/(\nu \times_c \sigma)$. This is effected by the following definition (where "s" stands for "simple"):

***305·01.** $X \times_s Y = \hat{R}\hat{S}\{(\exists \mu, \nu, \rho, \sigma) . \mu, \nu, \rho, \sigma \in \text{NC ind} . \nu \neq 0 . \sigma \neq 0 .$
$X = \mu/\nu . Y = \rho/\sigma . R \{(\mu \times_c \rho)/(\nu \times_c \sigma)\} S\}$ Df

which gives us

***305·142.** $\vdash : \mu, \rho \in \text{NC ind} . \nu \neq 0 . \sigma \neq 0 . \supset . \mu/\nu \times_s \rho/\sigma = (\mu \times_c \rho)/(\nu \times_c \sigma)$

and

***305·144.** $\vdash : \dot{\exists} ! (\mu/\nu \times_s \rho/\sigma) . \supset . \mu/\nu \times_s \rho/\sigma = (\mu \times_c \rho)/(\nu \times_c \sigma)$

The reason for the hypotheses in these propositions is that, if μ is a cardinal which is not inductive, while $\rho = 0$ and ν, σ are inductive and not 0, $\mu/\nu = \dot{\Lambda}$ and $\mu/\nu \times_s \rho/\sigma = \dot{\Lambda}$, but $(\mu \times_c \rho)/(\nu \times_c \sigma) = 0_q$.

For the applications of the multiplication of ratios, it is essential that we should have, if R, S, T belong to a suitable vector family,

$$R (\mu/\nu) S . S (\rho/\sigma) T . \supset . R (\mu/\nu \times_s \rho/\sigma) T,$$

e.g. we want two-thirds of five-sevenths of T to be $(2/3 \times_s 5/7)$ of T. It will be shown in Section C that our definition satisfies this requirement.

We prove in this number

***305·3.** $\vdash : X, Y \in \text{Rat} . \equiv . X \times_s Y \in \text{Rat}$

***305·22.** $\vdash :. X \times_s Y = 0_q . \equiv : X, Y \in \text{Rat} : X = 0_q . \vee . Y = 0_q$

i.e. a product only vanishes when one of its factors vanishes;

***305·301.** $\vdash : X, Y \in \text{Rat} - \iota`0_q . \equiv . X \times_s Y \in \text{Rat} - \iota`0_q$

***305·25.** $\vdash : \mu, \nu, \rho, \sigma \in \mathrm{D}`U \cap \mathrm{G}`U . \supset . (\mu/\nu \times_s \rho/\sigma) \upharpoonright t_{00}`\mu \in C`H$

Thus a product of two ratios which both exist in a given type exists in the next type, *i.e.*

***305·26.** $\vdash : X, Y \in \mathrm{Rat} . X \upharpoonright t_{11}`\mu, Y \upharpoonright t_{11}`\mu \in \mathrm{Rat\ def} . \supset . (X \times_s Y) \upharpoonright t_{00}`\mu \in C`H$

The formal laws offer no difficulty. We prove the commutative law (*305·11) and the associative law (*305·41); we prove that $X \times_s 1/1 = X$ (*305·51) and that $X \times_s \breve{X} = 1/1$ (*305·52). Division results from

***305·61.** $\vdash :. A \in \mathrm{Rat} - \iota`0_q . A' \in \mathrm{Rat} . \supset : A \times_s X = A' . \equiv . X = A' \times_s \breve{A}$

and the axiom of Archimedes is given by

$\vdash . (1) . (2) . \supset \vdash . \text{Prop}$

The condition $\mu \neq 0 . \rho \neq 0$ is required in the above proposition because if, *e.g.* $\mu = 0 . \rho \epsilon \text{NC infin}$, we shall have (if $\nu, \sigma \epsilon \text{NC ind} - \iota`0$) $\mu/\nu = 0_q . \rho/\sigma = \dot{\Lambda}$, whence $\mu/\nu \times_c \rho/\sigma = \dot{\Lambda}$, but $(\mu \times_c \rho)/(\nu \times_c \sigma) = 0_q$. If we assume $\mu, \rho \epsilon \text{NC ind}$, it is not necessary to assume $\mu \neq 0 . \rho \neq 0$. This is stated in *305·142.

Summary of *306.

The addition of simple ratios is treated in a way analogous to that in which their multiplication is treated. We wish to secure that the sum of λ/ν and μ/ν shall be $(\lambda +_c \mu)/\nu$, and that the sum of μ/ν and ρ/σ shall be $\{(\mu \times_c \sigma) +_c (\nu \times_c \rho)\}/(\nu \times_c \sigma)$. This is secured by the definition

***306·01.** $X +_s Y = \hat{R}\hat{S}\,[(\exists \mu, \nu, \rho) \,.\, \mu, \nu, \rho \,\epsilon\, \mathrm{NC\,ind} \,.\, \nu \neq 0 \,.$
$X = \mu/\nu \,.\, Y = \rho/\nu \,.\, R\,\{(\mu +_c \rho)/\nu\}\,S]$ Df

whence we obtain

***306·13.** $\vdash : \nu \neq 0 \,.\supset .\, \mu/\nu +_s \rho/\nu = (\mu +_c \rho)/\nu$

***306·14.** $\vdash : \nu \neq 0 \,.\, \sigma \neq 0 \,.\supset .\, \mu/\nu +_s \rho/\sigma = \{(\mu \times_c \sigma) +_c (\nu \times_c \rho)\}/(\nu \times_c \sigma)$

Our definition is so framed that $\infty_q +_s \infty_q = \Lambda$. This is on the whole convenient, though we could, of course, frame our definition so as to have $\infty_q +_s \infty_q = \infty_q$.

In applications, if R, S, T are members of a suitable vector-family, we want to have

$$R\,(\mu/\nu)\,T \,.\, S\,(\rho/\sigma)\,T \,.\supset .\, (R \,|\, S)\,(\mu/\nu +_s \rho/\sigma)\,T,$$

e.g. if a vector R is $2/3$ of T, and a vector S is $5/7$ of T, we want the vector which consists of first travelling a distance R and then travelling a distance S to be $(2/3 +_s 5/7)$ of T. We shall show in Section C that our definition of addition fulfils this requirement.

As in the case of products, the sum of two ratios is a ratio (*306·22), and the sum of two ratios which exist in a given type exists in the next type (*306·64). A ratio is unchanged by the addition of 0_q (*306·24), and a sum of two ratios is only 0_q if both the summands are 0_q (*306·2). No difficulty is offered by the formal laws: we prove the commutative law (*306·11), the associative law (*306·31), and the distributive law (*306·41).

An important proposition is

***306·52.** $\vdash :.\, X <_r Y \,.\equiv :\, X \,\epsilon\, \mathrm{Rat} : (\exists Z) \,.\, Z \,\epsilon\, \mathrm{Rat} - \iota`0_q \,.\, X +_s Z = Y$

When the axiom of infinity is assumed, this proposition becomes

$$XH'Y \,.\equiv :\, X \,\epsilon\, C`H' : (\exists Z) \,.\, Z \,\epsilon\, C`H \,.\, X +_s Z = Y.$$

We prove also the proposition upon which subtraction depends, namely

***306·54.** $\vdash :. X, Y \epsilon \mathrm{Rat} . \supset : X +_s Y = X +_s Z . \equiv . Y = Z$

***306·01.** $X +_s Y = \hat{R}\hat{S}\{(\exists \mu, \nu, \rho) . \mu, \nu, \rho \epsilon \mathrm{NC\,ind} . \nu \neq 0 .$
$X = \mu/\nu . Y = \rho/\nu . R\{(\mu +_c \rho)/\nu\} S\}$ Df

***306·1.** $\vdash : R(X +_s Y) S . \equiv . (\exists \mu, \nu, \rho) . \mu, \nu, \rho \epsilon \mathrm{NC\,ind} . \nu \neq 0 .$

*307. GENERALIZED RATIOS.

Summary of *307.

In this number we introduce negative ratios. If X is a ratio, what would ordinarily be called $-X$ is $X \mid \text{Cnv}$. This may be seen as follows. Suppose we have RXS. We then have $R(X \mid \text{Cnv})\breve{S}$. Now if R and S are vectors which carry us in the same direction, R and $\breve{S}$ are vectors which carry us in opposite directions, *i.e.* their ratio is negative. Hence calling the class of negative ratios "Rat_n," we may put

***307·01.** $\text{Rat}_n = \mid \text{Cnv}``\text{Rat}$ Df

The sum of "Rat" and "Rat_n" we will call "Rat_g," where "g" stands for "generalized." Thus we put

***307·011.** $\text{Rat}_g = \text{Rat} \cup \text{Rat}_n$ Df

If $\mu/\nu <_r \rho/\sigma$, we have $\{(\mu/\nu) \mid \text{Cnv}\} (\mid \text{Cnv} ; <_r) \{(\rho/\sigma) \mid \text{Cnv}\}$. Hence we put

***307·02.** $<_n = \mid \text{Cnv} ; <_r$ Df

***307·021.** $>_n = \text{Cnv}`<_n$ Df

If X and Y are generalized ratios, we consider X less than Y if either X, Y are both positive and $X <_r Y$, or X, Y are both negative and $X >_n Y$, or X is negative and Y is positive or zero. Hence we put

***307·03.** $<_g = (>_n) \cup (<_r) \cup (\text{Rat}_n - \iota`0_q) \uparrow \text{Rat}$ Df

On the analogy of $<_n$ and $<_g$, we put

***307·04.** $H_n = \mid \text{Cnv} ; H$ Df

***307·05.** $H_g = \breve{H}_n \ddagger H'$ Df

We prove in this number that if X is a ratio, $X \mid \text{Cnv} = \text{Cnv} \mid X$, and $\text{Cnv}`(X \mid \text{Cnv}) = \breve{X} \mid \text{Cnv}$ (*307·21·22). We prove also

***307·25.** $\vdash . C`H \cap C`H_n = \Lambda$

We prove that 0_q and ∞_q are their own negatives, but are not the negatives of anything else (*307·26·27·31). We prove $\text{Nr}`H_n = \text{Nr}`H$ (*307·41) and $\text{Infin ax} . \supset . H_g \in \eta$ (*307·46). None of the propositions of this number offer any difficulty.

This proposition requires $\eta \dot{+} \dot{1} \dot{+} \eta = \eta$, which is easily proved.

$*308$. ADDITION OF GENERALIZED RATIOS.

Summary of $*308$.

In this number we have to extend addition so as to include negative ratios as addenda, and for this purpose we have to define subtraction of simple ratios. This is defined as follows:

$$*308\cdot01.\quad X -_s Y = \hat{R}\hat{S}\{(\exists Z) : X, Y, Z \in \mathrm{Rat} : Z +_s Y = X \,.\, RZS \,.\, \mathsf{v} \,.\, Z +_s X = Y \,.\, RZ\breve{S}\} \quad \mathrm{Df}$$

That is to say, if $Y <_r X$, $X -_s Y$ is the ratio which must be added to Y to give X, while if $X <_r Y$, $X -_s Y$ is the negative of the ratio which must be added to X to give Y. Thus we have

$$*308\cdot13.\quad \vdash :. Y <_r X \,.\, \mathsf{v} \,.\, Y \in \mathrm{Rat} \,.\, Y = \dot{X} : \supset . X -_s Y = (\imath Z)(Z +_s Y = X)$$

$$*308\cdot14.\quad \vdash :. X <_r Y \,.\, \mathsf{v} \,.\, X \in \mathrm{Rat} \,.\, Y = X : \supset . X -_s Y = \{(\imath Z)(Z +_s X = Y)\} \,|\, \mathrm{Cnv}$$

We have, of course, $X -_s 0_q = X$ ($*308\cdot22$), $0_q -_s X = X \,|\, \mathrm{Cnv}$ ($*308\cdot23$), and $X -_s X = 0_q$ ($*308\cdot12$). Existence-theorems for $X -_s Y$ are closely analogous to those for $X +_s Y$ and $X \times_s Y$. Also we have

$$*308\cdot2.\quad \vdash : X, Y \in \mathrm{Rat} \,.\, \equiv . X -_s Y \in \mathrm{Rat}_g$$

We define the sum of two generalized ratios by means of the sums and differences of simple ratios, as follows:

$$*308\cdot02.\quad X +_g Y = (X +_s Y) \cup (X -_s Y \,|\, \mathrm{Cnv}) \cup (Y -_s X \,|\, \mathrm{Cnv}) \cup (X \,|\, \mathrm{Cnv} +_s Y \,|\, \mathrm{Cnv}) \,|\, \mathrm{Cnv} \quad \mathrm{Df}$$

Of the four relations which occur in the above definition, all but one must be null if neither X nor Y is 0_q. Thus if X and Y are positive, $X -_s Y \,|\, \mathrm{Cnv}$, $Y -_s X \,|\, \mathrm{Cnv}$, and $X \,|\, \mathrm{Cnv} +_s Y \,|\, \mathrm{Cnv}$ are null; if X is positive and Y negative, $X +_s Y$, $Y -_s X \,|\, \mathrm{Cnv}$, and $X \,|\, \mathrm{Cnv} +_s Y \,|\, \mathrm{Cnv}$ are null; if X and Y are both negative, $X +_s Y$, $X -_s Y \,|\, \mathrm{Cnv}$, and $Y -_s X \,|\, \mathrm{Cnv}$ are null.

If X is 0_q and Y is positive,

$$X +_s Y = Y -_s X \,|\, \mathrm{Cnv} \,.\, X -_s Y \,|\, \mathrm{Cnv} = (X \,|\, \mathrm{Cnv} +_s Y \,|\, \mathrm{Cnv}) \,|\, \mathrm{Cnv} = \dot{\Lambda}.$$

If both X and Y are 0_q, all four relations are 0_q.

Hence we find

***308·32.** $\vdash : X, Y \epsilon \text{Rat} . \supset . X +_g Y = X +_s Y$

***308·321.** $\vdash : X \epsilon \text{Rat} . Y \epsilon \text{Rat}_n . \supset . X +_g Y = X -_s Y \,|\, \text{Cnv}$

***308·322.** $\vdash : Y \epsilon \text{Rat} . X \epsilon \text{Rat}_n . \supset . X +_g Y = Y -_s X \,|\, \text{Cnv}$

***308·323.** $\vdash : X, Y \epsilon \text{Rat}_n . \supset . X +_g Y = (X \,|\, \text{Cnv} +_s Y \,|\, \text{Cnv}) \,|\, \text{Cnv}$

The existence-theorems for $X +_g Y$ are closely analogous to those for $X +_s Y$, and the formal laws offer no difficulty. We have

***308·52.** $\vdash :. X, Y \epsilon \text{Rat}_g . \supset : X +_g Y = X +_g Z . \equiv . Y = Z$

***308·54.** $\vdash : X, Y \epsilon \text{Rat}_g . \supset . (\exists Z) . Z \epsilon \text{Rat}_g . X +_g Z = Y$

$*309$. MULTIPLICATION OF GENERALIZED RATIOS.

Summary of $*309$.

The subject of this number is simpler than that of $*308$, because it requires nothing analogous to the consideration of subtraction. The product of two generalized ratios is defined as follows:

$*309\cdot01$. $X \times_g Y = (X \times_s Y) \cup (X \mid \text{Cnv} \times_s Y \mid \text{Cnv})$
$\cup (X \times_s Y \mid \text{Cnv}) \mid \text{Cnv} \cup (X \mid \text{Cnv} \times_s Y) \mid \text{Cnv}$ Df

As in $*308$, three of the four products concerned in this definition will be null in any given case (unless $X = 0_q$ or $Y = 0_q$). Hence

$*309\cdot14$. $\vdash : X, Y \in \text{Rat} . \supset . X \times_g Y = X \times_s Y$

$*309\cdot141$. $\vdash : X \in \text{Rat} . Y \in \text{Rat}_n . \supset . X \times_g Y = (X \times_s Y \mid \text{Cnv}) \mid \text{Cnv}$

$*309\cdot142$. $\vdash : Y \in \text{Rat} . X \in \text{Rat}_n . \supset . X \times_g Y = (X \mid \text{Cnv} \times_s Y) \mid \text{Cnv}$

$*309\cdot143$. $\vdash : X, Y \in \text{Rat}_n . \supset . X \times_g Y = X \mid \text{Cnv} \times_s Y \mid \text{Cnv}$

The propositions of this number are merely generalizations of those of $*305$. The proofs of the formal laws are straightforward, but the proof of the distributive law ($*309\cdot37$) is long, because of the multiplicity of different cases.

$*309\cdot01$. $X \times_g Y = (X \times_s Y) \cup (X \mid \text{Cnv} \times_s Y \mid \text{Cnv})$
$\cup (X \times_s Y \mid \text{Cnv}) \mid \text{Cnv} \cup (X \mid \text{Cnv} \times_s Y) \mid \text{Cnv}$ Df

$*309\cdot1$. $\vdash . X \times_g Y = (X \times_s Y) \cup (X \mid \text{Cnv} \times_s Y \mid \text{Cnv})$
$\cup (X \times_s Y \mid \text{Cnv}) \mid \text{Cnv} \cup (X \mid \text{Cnv} \times_s Y) \mid \text{Cnv}$ [($*309\cdot01$)]

$*310$. THE SERIES OF REAL NUMBERS.

Summary of $*310$.

Real numbers, as opposed to ratios, are required primarily in order to obtain a Dedekindian series, so as to secure limits to sets of rationals having no *rational* limit. If rationals and irrationals are to form one series, it is necessary to give some definition of "rationals" other than "ratios," since the series of ratios (assuming the axiom of infinity) is not Dedekindian, and is not part of any arithmetically definable Dedekindian series. But in virtue of the propositions of $*212$, the series of segments of the series of ratios, *i.e.* the series $\varsigma`H$, is Dedekindian, and this series contains a series, namely $\overrightarrow{H};H$, which is ordinally similar to H. Thus the properties which we desire real numbers to have will result if we identify them* with segments of H, and give the name "rational real numbers" to segments of the form $\overrightarrow{H}`X$, *i.e.* to segments which have ratios as limits. Thus $\overrightarrow{H}`X$ is the rational real number corresponding to the ratio X, and a real number in general is of the form $H``\lambda$, where $\lambda$ is a class of ratios. $H``\lambda$ will be *irrational* when λ has no limit or maximum in H.

Since real numbers involve *classes* of ratios, the ratios concerned must be of some one type, and cannot be typically indefinite. Thus, as might be expected, hardly any of the properties of real numbers can be proved without assuming the axiom of infinity. In the present number, however, we shall be mainly concerned with just those few simple properties which are independent of the axiom of infinity.

The series $\varsigma`H$, by which real numbers are to be defined, has both a beginning and an end, namely $\Lambda$ and $\mathrm{D}`H$ (which $= C`H$ if the axiom of infinity holds). $\mathrm{D}`H$ will be infinity among real numbers. It is not convenient to include it in the series of real numbers as defined, just as it was not convenient to include ∞_q in the series H or H'. Again Λ is not naturally to be taken as the zero of real numbers, which should rather be taken as being $\iota`0_q$. Thus we are led to the two following definitions, in which Θ is the series of positive real numbers other than zero and infinity,

* On this definition of real numbers, cf. *Principles of Mathematics*, Chap. XXXIII.

while Θ' is the series of zero and the positive real numbers other than infinity:

***310·01.** $\Theta = (\varsigma\text{‘}H) \upharpoonright (-\iota\text{‘}\Lambda - \iota\text{‘}\mathrm{D}\text{‘}H)$ Df

***310·011.** $\Theta' = \iota\text{‘}0_q \mathrel{\leftarrow\!\!\!\!+} \Theta$ Df

These notations are framed on the analogy of H and H', the letter Θ being chosen to suggest θ, the relation-number of the continuum. Although we do not have $\mathrm{Nr}\text{‘}\Theta = \theta$, we have $\mathrm{Nr}\text{‘}\varsigma\text{‘}H = \theta$, and therefore (*310·15) $\dot{1} \dotplus \mathrm{Nr}\text{‘}\Theta \dotplus \dot{1} = \theta$, and $\mathrm{Nr}\text{‘}\Theta' \dotplus \dot{1} = \theta$ (assuming the axiom of infinity). Thus the relation-number of Θ is simply that of a θ with the ends cut off.

We put further, on the analogy of H_n, H_g,

***310·02.** $\Theta_n = (\varsigma\text{‘}H_n) \upharpoonright (-\iota\text{‘}\Lambda - \iota\text{‘}\mathrm{D}\text{‘}H_n)$ Df

***310·021.** $\Theta'_n = \iota\text{‘}0_q \mathrel{\leftarrow\!\!\!\!+} \Theta_n$ Df

***310·03.** $\Theta_g = \breve{\Theta}_n \mathbin{\ddagger} \Theta'$ Df

Thus Θ_n is the series of negative real numbers, Θ'_n the series of zero and the negative real numbers, Θ_g the series of negative and positive real numbers including zero (infinity always excluded). The *class* of positive real numbers is $C\text{‘}\Theta$, of negative real numbers $C\text{‘}\Theta_n$, of all real numbers (excluding infinity) $C\text{‘}\Theta \cup \iota\text{‘}\iota\text{‘}0_q \cup C\text{‘}\Theta_n$. If ν is a positive real number, $|\mathrm{Cnv}\text{‘‘}\nu$ is the corresponding negative real number (*310·16). The properties of Θ, Θ_n, Θ_g in respect of limits, continuity, etc., result from the properties of θ as proved in *275, and from the properties of series of segments as proved in *212.

Instead of taking the series of segments as constituting the real numbers, it is possible to take the series of their relational sums, *i.e.* $\dot{s};\Theta$. This depends on the fact that $\dot{s};\Theta \mathrel{\mathrm{smor}} \Theta$ (*310·33). The chief advantage of $\dot{s};\Theta$ is that it is of the same type as the series of ratios. We shall show in *314 how to construct the arithmetic of real numbers defined as the relational sums of segments; until then, we shall regard real numbers as segments of the series of ratios.

$*311$. ADDITION OF CONCORDANT REAL NUMBERS.

Summary of $*311$.

We define a set of real numbers as *concordant* when all are positive or zero, or all are negative or zero, *i.e.* when all belong to $C'\Theta'$ or all belong to $C'\Theta'_n$. Given two concordant real numbers μ and ν, we define the sum of μ and ν as the class of sums, in the sense of $*308$, of a member of μ and a member of ν, *i.e.* as

$$\hat{W}\{(\exists M, N) \,.\, M \epsilon \mu \,.\, N \epsilon \nu \,.\, W = M +_g N\},$$

i.e. as $s'\mu \underset{,,}{+_g}{}''\nu$, in virtue of $*40\cdot7$. It is easy to prove that, assuming the axiom of infinity, the sum so defined has the properties we require of a sum. We denote the sum so defined by "$\mu +_p \nu$." In order to insure that $\mu +_p \nu$ shall be Λ unless μ, ν are concordant real numbers, we put

$*311\cdot02$. $\mu +_p \nu = \hat{X}\{\text{concord}(\mu, \nu) \,.\, X \epsilon s'\mu \underset{,,}{+_g}{}''\nu\}$ Df

Thus if μ, ν are concordant real numbers, $\mu +_p \nu = s'\mu \underset{,,}{+_g}{}''\nu$ ($*311\cdot11$); if not, $\mu +_p \nu = \Lambda$ ($*311\cdot1$). A definition of addition which applies to real numbers of opposite sign will be given in $*312$.

The commutative and associative laws for $+_p$ ($*311\cdot12\cdot121$) follow at once from the corresponding laws for $+_g$. Assuming the axiom of infinity, we prove without much difficulty that the sum of two positive real numbers is a positive real number ($*311\cdot27$), and the sum of two negative real numbers is a negative real number ($*311\cdot42$). In these proofs, when propositions of previous numbers involving "Rat" are used, "Rat" is replaced by $C'H'$ and "$\text{Rat} - \iota'0_q$" by $C'H$. This is legitimate in virtue of $*304\cdot49\cdot34$. In $*311\cdot511$ we prove (assuming the axiom of infinity) that if ξ is a positive real number, and Y is any positive ratio, however small, there are members X of ξ such that $Y +_g X$ is not a member of ξ, *i.e.* given any positive real number, there are rationals differing from it by less than any assigned positive rational. This proposition is useful, and is used in proving that if ξ, η are positive real numbers, each is less than $\xi +_p \eta$ ($*311\cdot52$). The converse of this proposition, *i.e.* the proposition that, if $\mu\Theta\nu$, there is a positive real number

λ such that $\nu = \mu +_p \lambda$, is proved in $*311{\cdot}621{\cdot}64$, after a considerable amount of work. Thus we have

$*311{\cdot}65$. $\vdash :: \text{Infin ax} . \supset :. \mu \Theta \nu . \equiv : \mu, \nu \in C`\Theta : (\exists \lambda) . \lambda \in C`\Theta . \nu = \mu +_p \lambda$

We have, of course, a corresponding proposition for Θ_n ($*311{\cdot}66$). From $*311{\cdot}65$ we deduce without difficulty that if μ is less than ν (μ, ν being positive real numbers), then $\lambda +_p \mu$ is less than $\lambda +_p \nu$ (λ being a positive real number), *i.e.*

$*311{\cdot}73$. $\vdash : \text{Infin ax} . \lambda \in C`\Theta . \mu \Theta \nu . \supset . (\lambda +_p \mu) \Theta (\lambda +_p \nu)$

whence (with the corresponding proposition for Θ_n) we deduce

$*311{\cdot}75$. $\vdash :. \text{Infin ax} . \text{concord}(\lambda, \mu) . \supset : \lambda +_p \mu = \lambda +_p \nu . \equiv . \mu = \nu$

which secures the uniqueness of subtraction.

$*312$. ALGEBRAIC ADDITION OF REAL NUMBERS.

Summary of $*312$.

In this number we extend the definition of addition so as to apply to real numbers of opposite sign. As in $*308$, this requires a previous definition of subtraction. We define subtraction as follows: If there is a λ such that $\nu +_p \lambda = \mu$, then $\mu -_p \nu$ is λ; if there is a λ such that $\mu +_p \lambda = \nu$, then $\mu -_p \nu$ is $\mid \mathrm{Cnv}``\lambda$, *i.e.* the negative of λ; in any other case, $\mu -_p \nu = \Lambda$. The formal definition is:

$$*312\cdot01.\quad \mu -_p \nu = \hat{X}\{(\exists\lambda) : \lambda, \mu, \nu \in C`\Theta_g : \nu +_p \lambda = \mu \,.\, X \in \lambda \,.\vee.\, \mu +_p \lambda = \nu \,.\, X \in \mid \mathrm{Cnv}``\lambda\} \quad \mathrm{Df}$$

Hence assuming the axiom of infinity we have

$$\nu\,(\Theta \cup \Theta_n)\,\mu \,.\supset.\, \mu -_p \nu = (\imath\lambda)\,(\nu +_p \lambda = \mu) \quad (*312\cdot18),$$

$$\mu\,(\Theta \cup \Theta_n)\,\nu \,.\supset.\, \mu -_p \nu = (\imath\lambda)\,(\mu +_p \mid \mathrm{Cnv}``\lambda = \nu) \quad (*312\cdot181),$$

$$\lambda \in C`\Theta_g \,.\supset.\, \lambda -_p \lambda = \iota`0_q \quad (*312\cdot191).$$

The algebraic sum of μ and ν is defined as $\mu +_p \nu$ if μ and ν are of the same sign, and as $\mu -_p \mid \mathrm{Cnv}``\nu$ if μ and ν are of opposite signs; *i.e.* we put

$$*312\cdot02.\quad \mu +_a \nu = (\mu +_p \nu) \cup (\mu -_p \mid \mathrm{Cnv}``\nu) \quad \mathrm{Df}$$

This definition is justified because either $\mu +_p \nu$ or $\mu -_p \mid \mathrm{Cnv}``\nu$ must always be Λ. Thus we have

$$*312\cdot32.\quad \vdash : \mathrm{concord}\,(\mu, \nu) \,.\supset.\, \mu +_a \nu = \mu +_p \nu$$

$$*312\cdot33.\quad \vdash : \sim \mathrm{concord}\,(\mu, \nu) \,.\supset.\, \mu +_a \nu = \mu -_p \mid \mathrm{Cnv}``\nu$$

The propositions proved are analogous to those of previous numbers, and offer no difficulty.

$$*312\cdot01.\quad \mu -_p \nu = \hat{X}\{(\exists\lambda) : \lambda, \mu, \nu \in C`\Theta_g : \nu +_p \lambda = \mu \,.\, X \in \lambda \,.\vee.\, \mu +_p \lambda = \nu \,.\, X \in \mid \mathrm{Cnv}``\lambda\} \quad \mathrm{Df}$$

$$*312\cdot02.\quad \mu +_a \nu = (\mu +_p \nu) \cup (\mu -_p \mid \mathrm{Cnv}``\nu) \quad \mathrm{Df}$$

$*313$. MULTIPLICATION OF REAL NUMBERS.

Summary of $*313$.

Multiplication of real numbers is simpler than addition, because it is not necessary to distinguish between factors of the same sign and factors of opposite signs. Thus we put

$*313{\cdot}01$. $\mu \times_a \nu = \hat{X}\{\mu, \nu \in C`\Theta_g \,.\, X \in s`\mu \underset{\prime\prime}{\times_g}{}``\nu\}$ Df

Thus if μ, ν are real numbers, their product is the class of products (in the sense of $*309$) of members of μ and members of ν; otherwise their product is Λ. The propositions of this number are analogous to those of previous numbers, and the proofs are as a rule analogous to those of $*311$, except in the case of the distributive law ($*313{\cdot}55$).

$*313{\cdot}01$. $\mu \times_a \nu = \hat{X}\{\mu, \nu \in C`\Theta_g \,.\, X \in s`\mu \underset{\prime\prime}{\times_g}{}``\nu\}$ Df

Proofs in this number are mostly analogous to those for addition, and are therefore often omitted.

$*314$. REAL NUMBERS AS RELATIONS.

Summary of $*314$.

In this number we take up the definition of real numbers suggested in $*310$, namely $\dot{s}``C`\Theta_g$ instead of $C`\Theta_g$. The series of real numbers is now $\dot{s};\Theta_g$ instead of Θ_g. Everything in this number depends upon

$*310\cdot32$. $\vdash :. \mu, \nu \in C`\Theta_g . \supset : \dot{s}`\mu = \dot{s}`\nu . \equiv . \mu = \nu$

In consequence of this proposition, $\dot{s} \upharpoonright C`\Theta_g$ is a correlation of the two sorts of real numbers, and the properties of the relational sort can be immediately deduced from the propositions of previous numbers. We define addition and multiplication of relational real numbers so as to secure that, if μ, ν are real numbers of our previous sort, the arithmetical sum of $\dot{s}`\mu$ and $\dot{s}`\nu$ is $\dot{s}`(\mu +_a \nu)$ and their product is $\dot{s}`(\mu \times_a \nu)$. This is effected by putting

$*314\cdot01$. $X +_r Y = \hat{R}\hat{S}[(\exists\mu, \nu) . X = \dot{s}`\mu . Y = \dot{s}`\nu . R\{\dot{s}`(\mu +_a \nu)\} S]$ Df

with a similar definition for $X \times_r Y$. The zero of real numbers is now 0_q instead of $\iota`0_q$, and the negative of a real number X is $X \mid \mathrm{Cnv}$. The fundamental propositions are

$*314\cdot13$. $\vdash : \mu, \nu \in C`\Theta_g . \supset . \dot{s}`\mu +_r \dot{s}`\nu = \dot{s}`(\mu +_a \nu)$

$*314\cdot14$. $\vdash : \mu, \nu \in C`\Theta_g . \supset . \dot{s}`\mu \times_r \dot{s}`\nu = \dot{s}`(\mu \times_a \nu)$

in virtue of which the arithmetical properties of relational real numbers follow at once from those of real numbers as segments.

Relational real numbers are useful in applying measurement by means of real numbers to vector-families, since it is convenient to have real numbers of the same type as ratios.

For some purposes, a somewhat different definition of real numbers as relations is more convenient. Instead of deriving our relations from Θ_g, we may derive them from $\varsigma`H_g$, *i.e.* we may consider the relations $\dot{s}``C`\varsigma`H_g$ instead of the relations $\dot{s}``C`\Theta_g$. In virtue of $*217\cdot43$, $(\varsigma`H_g) \upharpoonright (-\iota`\Lambda - \iota`C`H_g)$ is ordinally similar to Θ_g; hence the requisite properties of $\dot{s}``C`\varsigma`H_g$ follow at once.

***314·51.** $\vdash :$ Infin ax $. \mu, \nu \in C`\Theta_g . \supset .$

$\dot{s}`♂`\mu +_\sigma \dot{s}`♂`\nu = \dot{s}`♂`(\mu +_a \nu) . \dot{s}`♂`\mu \times_\sigma \dot{s}`♂`\nu = \dot{s}`♂`(\mu \times_a \nu)$
[*314·42 . (*314·04·05)]

The properties of $M +_\sigma N$ and $M \times_\sigma N$ result from this proposition exactly as those of $X +_r Y$ and $X \times_r Y$ result from *314·13·14.

SECTION B.

VECTOR-FAMILIES.

Summary of Section B.

The present Section is concerned with the theory of magnitude, so far as this can be developed without measurement. Measurement—*i.e.* the application of ratios and real numbers to magnitudes—will be dealt with in Section C; for the present, we shall confine ourselves to those properties of magnitude which are presupposed in measurement. But throughout this Section, measurement is the goal: the hypotheses introduced and the propositions proved will be such as are relevant to the possibility of measurement.

We conceive a magnitude as a vector, *i.e.* as an operation, *i.e.* as a descriptive function in the sense of $*30$. Thus for example, we shall so define our terms that 1 gramme would not be a magnitude, but the difference between 2 grammes and 1 gramme would be a magnitude, *i.e.* the relation "$+1$ gramme" would be a magnitude. On the other hand a centimetre and a second will both be magnitudes according to our definition, because distances in space and time are vectors. It will be remembered that we defined ratios as relations between relations; hence if ratios are to hold between magnitudes, magnitudes must be taken as relations.

We demand of a vector (1) that it shall be a one-one relation, (2) that it shall be capable of indefinite repetition, *i.e.* that if the vector takes us from a to b, there shall always be a point c such that the vector takes us from b to c. If R is the vector, the point to which it takes us from a is $R'a$; thus the above requisite is expressed by "$\mathrm{E}\,!\,R'a \,.\supset_a.\, \mathrm{E}\,!\,R'R'a$," *i.e.* by "$\mathrm{D}'R \subset \text{ꓷ}'R$." It will be observed that the points which are starting-points of the vector form the class $\text{ꓷ}'R$, *i.e.* the class of possible arguments to R considered as a descriptive function, while the points which are the end-points of the vector form the class $\mathrm{D}'R$, *i.e.* the class of values of R considered as a descriptive function. Since $\mathrm{D}'R \subset \text{ꓷ}'R$, we have $\text{ꓷ}'R = C'R$; thus the field of the vector consists of all points from which the vector can start. By

assuming $D`R \subset \text{ɑ}`R$, we exclude magnitudes of kinds which have a definite maximum, unless they are circular, like the angles at a point or the distances on an elliptic straight line; but, except when they are circular, such magnitudes are of little importance.

According to what has just been said, if R is a vector whose field is α, we have

$$R \epsilon 1 \to 1 \,.\, \text{ɑ}`R = \alpha \,.\, D`R \subset \alpha.$$

A relation which fulfils this hypothesis is called a "correspondence" of α, because it makes a part of α correspond with α. The class of correspondences of α we denote by "cr$`\alpha$," which is the cardinal correlative of "cror$`P$," defined in *208. Thus we put

$$\text{cr}`\alpha = (1 \to 1) \cap \overleftarrow{\text{ɑ}}`\alpha \cap \breve{D}``\text{Cl}`\alpha \quad \text{Df.}$$

We proceed next to define a vector-family of α." This we define as an existent sub-class of cr$`\alpha$ such that, if R and S are any two members of it, $R \mid S = S \mid R$. We define a class of relations as "Abelian" when the relative product of any two members of the class is commutative, *i.e.* we put

$$\text{Abel} = \hat{\kappa}\,(R, S \epsilon \kappa \,.\, \supset_{R,S} \,.\, R \mid S = S \mid R) \quad \text{Df.}$$

Thus a vector-family of α is an existent Abelian sub-class of cr$`\alpha$, *i.e.* writing "fm$`\alpha$" for "vector-family of α," we put

$$\text{fm}`\alpha = \text{Abel} \cap \text{Cl ex}`\text{cr}`\alpha \quad \text{Df.}$$

The class of vector-families is then defined as everything which is a vector-family of some α, *i.e.* we put

$$FM = s`D`\text{fm} \quad \text{Df.}$$

Thus a vector-family is an existent Abelian class of one-one relations which all have the same converse domain, and all have their domains contained in this common converse domain. If κ is a vector-family, the common converse domain is $\breve{\iota}`\text{ɑ}``\kappa$, which is identical with $s`\text{ɑ}``\kappa$, and will be called the "field" of the family. Thus we have

$$\vdash : \kappa \epsilon FM \,.\, \equiv \,.\, \kappa \epsilon \text{Abel} \,.\, \kappa \subset 1 \to 1 \,.\, \text{ɑ}``\kappa \epsilon 1 \,.\, s`D``\kappa \subset s`\text{ɑ}``\kappa.$$

A vector-family may be regarded as a kind of magnitude. In order to render measurement possible, we require various hypotheses as to the nature of the family. Measurement within a given family κ is obtained by limiting the fields of ratios to κ, *i.e.* by considering $X \upharpoonright \kappa$ where X is a ratio, or $Z \upharpoonright \kappa$ where Z is a relational real number of the kind defined in *314. In order to make measurement possible, we wish κ to be such that, if X is a ratio, $X \upharpoonright \kappa$ shall be one-one; again, if R, S, T are members of κ, and R has the ratio X to S, while S has the ratio Y to T, we wish R to have the ratio $X \times_s Y$ to T, *i.e.* we wish to have

$$X \upharpoonright \kappa \mid Y \upharpoonright \kappa \subseteq (X \times_s Y) \upharpoonright \kappa\,;$$

again, if R has the ratio X to T, and S has the ratio Y to T, we wish $R \mid S$ (which represents the "sum" of R and S) to have the ratio $X +_s Y$ to T, *i.e.* we wish to have

$$(X \lceil \kappa`T) \mid (Y \lceil \kappa`T) \subset (X +_s Y) \lceil \kappa`T.$$

The above and other similar properties will be proved, with suitable hypotheses, in Section C; for the present, we shall proceed with the theory of vector-families without explicit regard to measurement.

The first and most important hypothesis as to a family which we consider is the hypothesis that it is "connected," *i.e.* that there is at least one member of its field from which we can reach any member of the field by a vector belonging to the family or by the converse of a vector belonging to the family. Such a member of the field of κ we shall call a "connected point" of κ; the class of such points will be denoted by "conx$`\kappa$"; the definition is

$$\mathrm{conx}`\kappa = s`\mathrm{C}``\kappa \cap \hat{a}\,(\overrightarrow{\dot{s}`\kappa}`a \cup \overleftarrow{\dot{s}`\kappa}`a = s`\mathrm{C}``\kappa) \quad \mathrm{Df.}$$

It will be observed that $\overrightarrow{\dot{s}`\kappa}`a$ are the points to which there is a vector from a, while $\overleftarrow{\dot{s}`\kappa}`a$ are the points from which there is a vector to a. The definition states that these two classes together make up the whole field of the family. We define a connected family as one which has at least one connected point, *i.e.* we put

$$FM\,\mathrm{conx} = FM \cap \hat{\kappa}\,(\exists\,!\,\mathrm{conx}`\kappa) \quad \mathrm{Df.}$$

The properties of connected families are many and important. Among these may be mentioned the following: If κ is a connected family, the logical product of any two different members of κ is null, *i.e.* if $P, Q \in \kappa \,.\, P \neq Q$, then $P \dot{\cap} Q = \dot{\Lambda}$, or, what comes to the same thing, if $P, Q \in \kappa$, and if we ever have $P`x = Q`x$, then $P = Q$; if $P \in \kappa$, all the powers of P are either members of κ or the converses of members; if $P, Q \in \kappa$, then $P \mid Q$ is either a member of κ or the converse of a member. A connected family may not form a group, *i.e.* we do not necessarily have

$$P, Q \in \kappa \,.\, \supset_{P,Q} .\, P \mid Q \in \kappa,$$

but we shall show at a later stage (*354) that a group can be derived from a connected family κ by merely adding to it the converses of those members of κ (if any) whose domains are equal to their converse domains. The result of this addition is to give us a connected family which is a group.

Another important property of a connected family κ is that $I \upharpoonright s`\mathrm{C}``\kappa$ is always a member of it. $I \upharpoonright s`\mathrm{C}``\kappa$ is the zero vector. In a connected family, every vector except $I \upharpoonright s`\mathrm{C}``\kappa$ is contained in diversity. For many purposes, the class of vectors excluding $I \upharpoonright s`\mathrm{C}``\kappa$ is important. We therefore put

$$\kappa_\partial = \kappa - \mathrm{Rl}`I \quad \mathrm{Df.}$$

In the study of a vector-family κ, an important derived class of relations is the class of all relations of the form $\breve{R} | S$, where $R, S \epsilon \kappa$. The operation $\breve{R} | S$ consists of an S-step forward, followed by an R-step backward; that is to say, if $\breve{R}‘S‘a$ exists, it is obtained by moving a distance S forward from a to $S‘a$, and then a distance R backward from $S‘a$ to $\breve{R}‘S‘a$. The class of such relations as $\breve{R} | S$, where $R, S \epsilon \kappa$, we call κ_ι; *i.e.* we put

$$\kappa_\iota = s‘(\mathrm{Cnv}‘‘\kappa) |_{,,}‘‘\kappa \quad \mathrm{Df.}$$

The class κ_ι will have different properties according to the nature of κ. We may distinguish three cases:

(1) The field of κ may have a first term, *i.e.* there may be a member of $s‘\mathrm{Cl}‘‘\kappa$ which is not a member of $s‘\mathrm{D}‘‘\kappa_\partial$. This case is illustrated, *e.g.* by a family of distances from left to right on the portion of a given line not lying to the left of a given point. This given point will then belong to $s‘\mathrm{Cl}‘‘\kappa$, since there are vectors which start from it, but it will not belong to $s‘\mathrm{D}‘‘\kappa_\partial$, since there are no vectors which end at it except the zero vector. A connected point a which belongs to $s‘\mathrm{Cl}‘‘\kappa$ but not to $s‘\mathrm{D}‘‘\kappa_\partial$ is called the "initial" point, and a family which has an initial point is called an "initial" family. A family cannot have more than one initial point. Thus we put

$$\mathrm{init}‘\kappa = \breve{\iota}‘(\mathrm{conx}‘\kappa - s‘\mathrm{D}‘‘\kappa_\partial) \quad \mathrm{Df,}$$

$$FM\,\mathrm{init} = FM \cap \mathrm{Cl}‘\mathrm{init} \quad \mathrm{Df.}$$

(2) It may happen that, even if κ is not an initial family, none of the converses of members of κ_∂ are members of κ. (If κ is an initial family, this must happen.) This case is illustrated by the case of all distances towards the right on a straight line. It is also illustrated by the family of vectors of the form $(+_s X) \upharpoonright C‘H$, where $X \epsilon C‘H'$. In this case, as in (1), it is possible, by adding suitable hypotheses, to secure that $\dot{s}‘\kappa_\partial$ shall be a series. This case divides into two, which are illustrated by the above two instances: it may happen, as in our first instance, that the domain of a vector is always equal to its converse domain, *i.e.* $\mathrm{D}‘‘\kappa = \mathrm{Cl}‘‘\kappa$; or it may happen, as in our second instance, that the domain is only part of the converse domain. (The domain of $(+_s X) \upharpoonright C‘H$ consists of all ratios greater than X.)

(3) It may happen that κ_∂ contains pairs of vectors which are each other's converses. In this case, it is obvious that $\dot{s}‘\kappa_\partial$ cannot be serial, since $R, \breve{R} \epsilon \kappa_\partial . \supset . \breve{R} | R = I \upharpoonright s‘\mathrm{Cl}‘‘\kappa . \breve{R} | R \subset (\dot{s}‘\kappa_\partial)^2$, so that $(\dot{s}‘\kappa_\partial)^2$ is not contained in diversity (except in the trivial case $\kappa = \iota‘\dot{\Lambda}$).

In considering κ_ι, we do not at first explicitly introduce any of the above possibilities, but it is necessary to bear them in mind in order to realize the

purpose of the propositions proved concerning κ_ι. If L is a member of κ_ι, and $L = \breve{R} | S$, where $R, S \epsilon \kappa$, then if a is a connected point, and $L'a$ exists, it follows that there is a member T of $\kappa \cup \text{Cnv}``\kappa$ such that $L'a = T'a$. It is easy to deduce from this that $L = T$, hence $L \epsilon \kappa \cup \text{Cnv}``\kappa$. The same holds if $\breve{L}'a$ exists. Hence if $\text{E} ! L'a . \vee . \text{E} ! \breve{L}'a$, *i.e.* if $a \epsilon C'L$, L is a member of $\kappa \cup \text{Cnv}``\kappa$. Thus if $a$ belongs to the field of every member of $\kappa_\iota$, we shall have $\kappa_\iota = \kappa \cup \text{Cnv}``\kappa$. We say that a family "has connexity" (not to be confounded with "being connected") if $\exists ! \text{conx}'\kappa \cap p'C``\kappa_\iota$; thus we put

$$FM\,\text{connex} = FM \cap \hat{\kappa}\,(\exists ! \text{conx}'\kappa \cap p'C``\kappa_\iota) \quad \text{Df}$$

and by what has just been said we have

$$\vdash : \kappa \epsilon FM\,\text{connex} . \supset . \kappa_\iota = \kappa \cup \text{Cnv}``\kappa.$$

We also have $\vdash : \kappa \epsilon FM\,\text{connex} . \supset . \dot{s}'\kappa_\partial \epsilon \text{connex}$

and $\vdash :. \kappa \epsilon FM\,\text{conx} . \supset : \kappa \epsilon FM\,\text{connex} . \equiv . \dot{s}'\kappa_\partial \epsilon \text{connex}.$

It is these propositions that justify the notation "*FM* connex."

It is obvious that we shall have $\exists ! p'C``\kappa_\iota$ if $\text{D}``\kappa = \text{Ɑ}``\kappa$, unless $\kappa = \iota'\dot{\Lambda}$.

Some illustrations will serve to make clearer the nature of the hypothesis $\exists ! p'C``\kappa_\iota$. This hypothesis states that there is at least one term a in the field of κ such that, if R, S are any two members of κ, we can either take an R-step forward from a, followed by an S-step backward, or we can take an S-step forward followed by an R-step backward. Suppose, for example, that our family consists of all vectors of the form $(+_0 \mu) \upharpoonright \text{NC induct}$, where $\mu \epsilon \text{NC induct}$. Then if R is the operation of adding μ, and S is the operation of adding ν, $\breve{R} | S$ is the operation of adding $\nu -_0 \mu$ if $\nu > \mu$, and is the operation of subtracting $\mu -_0 \nu$ if $\mu > \nu$. In the former case $\breve{R} | S \epsilon \kappa$, while in the latter case $\breve{S} | R \epsilon \kappa$. In the former case, if ϖ is any inductive cardinal, $(\breve{R} | S)'\varpi = \nu -_0 \mu +_0 \varpi$; in the latter case, $(\breve{S} | R)'\varpi = \mu -_0 \nu +_0 \varpi$. Thus in either case $\varpi \epsilon C'(\breve{R} | S)$. Thus the family in question has connexity, and $\kappa_\iota = \kappa \cup \text{Cnv}``\kappa$.

But now consider the family consisting of all vectors of the form $(\times_0 \mu) \upharpoonright (\text{NC induct} - \iota'0)$, where $\mu \epsilon \text{NC induct} - \iota'0$. This is an initial family, its initial point being 1. But it does not have connexity. If $R = (\times_0 \mu) \upharpoonright (\text{NC induct} - \iota'0)$ and $S = (\times_0 \nu) \upharpoonright (\text{NC induct} - \iota'\Lambda)$, $\breve{R} | S$ is the operation of multiplying by ν and dividing by μ, with its field confined to inductive cardinals other than 0. If ν is prime to μ, this relation has only multiples of μ in its converse domain and only multiples of ν in its domain. Hence its field consists of multiples of μ together with multiples of ν. Thus no member of κ_ι except $I \upharpoonright s'\text{Ɑ}``\kappa$, *i.e.* $(\times_0 1) \upharpoonright (\text{NC induct} - \iota'0)$, has the whole of $s'\text{Ɑ}``\kappa$ for its field, and there is no number which belongs to the

field of every member of κ_ι. The above family may be usefully borne in mind in considering κ_ι, since it affords good illustrations of most of the general theorems concerning κ_ι.

If κ is any family except $\iota`\Lambda$, any finite number of members of $\kappa_\iota$ have an existent relative product, and their converse domains have an existent logical product. If $\kappa$ is a connected family, any two members $L, M$ of $\kappa_\iota$ whose logical product exists, *i.e.* for which $(\exists y) . L`y = M`y$, are identical, and if $x, y$ are any two members of $s`\mathrm{C}``\kappa$, there is just one member of κ_ι such that $x = L`y$. If $M \epsilon \kappa_\iota$ and P is a power of M, there is some member L of κ_ι such that $P \subset L$. But P is not in general itself a member of κ_ι. For the application of ratio, the member of κ_ι which contains P is important. We call it the "representative" of P. The general definition of a representative is

$$\mathrm{rep}_\kappa`P = \dot{s}`(\kappa_\iota \cap \overleftarrow{\subset}`P) \quad \mathrm{Df.}$$

In a connected family, $\kappa_\iota \cap \overleftarrow{\subset}`P$ cannot have more than one member; hence if there is any member of $\kappa_\iota$ which contains $P$, that member is $\mathrm{rep}_\kappa`P$, and if there is no member of κ_ι which contains P, $\mathrm{rep}_\kappa`P = \dot{\Lambda}$.

If $\breve{P} \mid Q$ is any member of κ_ι (where $P, Q \epsilon \kappa$), we shall have

$$\mathrm{rep}_\kappa`(\breve{P} \mid Q)^\rho = \breve{P}^\rho \mid Q^\rho;$$

and if $L, M \epsilon \kappa_\iota$, we shall have

$$\mathrm{rep}_\kappa`(L \mid M)^\rho = \mathrm{rep}_\kappa`(L^\rho \mid M^\rho) = \mathrm{rep}_\kappa`\{(\mathrm{rep}_\kappa`L^\rho) \mid (\mathrm{rep}_\kappa`M^\rho)\}.$$

These two formulae are the most useful in determining representatives.

In order to apply the above theory to the measurement of vectors, it is necessary to distinguish between open and cyclic families. An open family is one in which, if $M \epsilon \kappa_\iota - \mathrm{Rl}`I$, $M_{\mathrm{po}} \subset J$, *i.e.* one in which no number of repetitions of a non-zero member of κ_ι will bring us back to our starting-point. If this condition fails, as in the case of angles, or distances on the elliptic straight line, the problem of measurement is more complicated, since, if θ is a measure of an angle, so is $2\nu\pi + \theta$ for any integral ν. The case of cyclic families will be considered in Section D; for the present, we proceed to consider open families, and we shall still be concerned almost exclusively with open families in Section C. It should be observed that in cyclic families, as we shall define them, members of κ_∂ return into themselves, whereas in open families, not merely no member of κ_∂, but no member of $\kappa_\iota - \mathrm{Rl}`I$, returns into itself. In most of the families that naturally occur, it happens either that no member of $\kappa_\iota - \mathrm{Rl}`I$ returns into itself, or that there are members of κ_∂ which do so. But there is no logical necessity in this, as the following instance shows: Consider the family consisting of positive and negative integral multipliers other than -1, with their fields confined to positive and negative integers other than -1. Then 1 is a

connected point of this family, in fact the initial point. Multiplication by -1 is a member of κ_ι, since it can be obtained by multiplying by any integer μ and then dividing by $-\mu$. Also the square of multiplication by -1 is contained in identity, and is the zero vector of our family. Hence there is a member of $\kappa_\iota - \mathrm{Rl}`I$ whose square is contained in identity, although no power of any member of κ_∂ is contained in identity.

In order to avoid brackets, we put

$$\kappa_{\iota\partial} = (\kappa_\iota)_\partial \quad \mathrm{Df},$$

i.e.

$$\kappa_{\iota\partial} = \kappa_\iota - \mathrm{Rl}`I.$$

Then the definition of open families is

$$FM\,\mathrm{ap} = FM \cap \hat{\kappa}\,(s`\mathrm{Pot}``\kappa_{\iota\partial} \subset \mathrm{Rl}`J) \quad \mathrm{Df}.$$

Hence $\quad \vdash :. \kappa \in FM\,\mathrm{ap} . \equiv : \kappa \in FM : M \in \kappa_{\iota\partial} . \supset_M . M_{\mathrm{po}} \mathrel{\mathsf{G}} J.$

It will be observed that if κ is an open family, κ_ι is contained in Rel num id (cf. ∗300), and $\kappa_{\iota\partial} \subset$ Rel num. Hence if $M \in \kappa_{\iota\partial}$, $M^\nu = M_\nu$ (cf. ∗121), and the propositions on intervals in ∗121 become available. Also if $M \in \kappa_{\iota\partial}$, and $a \in s`\mathrm{C}``\kappa$, we have

$$\breve{M} \upharpoonright \overrightarrow{M_*}`a \in \mathrm{Prog} . \breve{M}_{\mathrm{po}} \upharpoonright \overrightarrow{M_*}`a \in \omega.$$

The chief use of these facts is to show that the existence of open families implies the axiom of infinity and the existence of $\aleph_0$. Hence as applied to open families, the theory of ratio undergoes the very great simplification which results from the axiom of infinity.

If κ is open and connected, and $L, M \in \kappa_\iota$, and σ is any inductive cardinal other than 0, we shall have $L = M$ if $L^\sigma = M^\sigma$ or $\mathrm{rep}_\kappa`L^\sigma = \mathrm{rep}_\kappa`M^\sigma$ or $\dot{\exists} ! L^\sigma \dot{\cap} M^\sigma$. If ρ, τ are also inductive cardinals other than 0, we shall have $\mathrm{rep}_\kappa`L^\rho = \mathrm{rep}_\kappa`M^\sigma$ if $L^{\rho \times_0 \tau} = M^{\sigma \times_0 \tau}$, or if $\mathrm{rep}_\kappa`L^{\rho \times_0 \tau} = \mathrm{rep}_\kappa`M^{\sigma \times_0 \tau}$, or if $\dot{\exists} ! L^{\rho \times_0 \tau} \dot{\cap} M^{\sigma \times_0 \tau}$. We have in fact

$$\mathrm{rep}_\kappa`L^\rho = \mathrm{rep}_\kappa`M^\sigma . \equiv . \dot{\exists} ! L^\rho \dot{\cap} M^\sigma$$
$$\equiv . \dot{\exists} ! L^{\rho \times_0 \tau} \dot{\cap} M^{\sigma \times_0 \tau}$$

and

$$\mathrm{rep}_\kappa`M^\rho = \mathrm{rep}_\kappa`M^\sigma . \equiv . M^\rho = M^\sigma . \equiv . \rho = \sigma.$$

On applying the definition of ratio (∗303·01), we see from the above propositions that, with the above hypothesis,

$$M\,(\rho/\sigma)\,N . \equiv . \dot{\exists} ! M^\sigma \dot{\cap} N^\rho . \equiv . \mathrm{rep}_\kappa`M^\sigma = \mathrm{rep}_\kappa`N^\rho,$$

while if R, T are members of κ,

$$R\,(\rho/\sigma)\,S . \equiv . R^\sigma = S^\rho.$$

Further, we have, in virtue of the above propositions,

$$\dot{\exists} ! L^\sigma \dot{\cap} M^\rho . \dot{\exists} ! L^\nu \dot{\cap} M^\mu . \supset . \mu \times_0 \sigma = \nu \times_0 \rho,$$

whence

$$X, Y \in C`H' . \dot{\exists} ! X \upharpoonright \kappa_{\iota\partial} \dot{\cap} Y \upharpoonright \kappa_{\iota\partial} . \supset . X = Y.$$

These propositions, together with

$$X \in C\text{`}H \,.\, \supset \,.\, X \upharpoonright \kappa_\iota \in 1 \rightarrow 1,$$

belong to Section C. They are mentioned here as showing why the propositions of this Section are useful in connection with measurement.

We next proceed to consider serial families, which are those in which $\dot{s}\text{`}\kappa_\partial$ is an existent serial relation. For this purpose we require the definition of "*FM* connex" already given, and also the definition of "transitive" families. We define a as a "transitive point" of κ if

$$(\dot{s}\text{`}\kappa_\partial)\text{``}\overrightarrow{\dot{s}\text{`}\kappa_\partial}\text{`}a \subset \overrightarrow{\dot{s}\text{`}\kappa_\partial}\text{`}a,$$

i.e. if any point which can be reached from a in two non-null steps can also be reached in one non-null step. We define a family as transitive when it has at least one transitive point. If $\kappa \in FM\,\text{conx}$, the hypothesis that κ is transitive is equivalent to the hypothesis that κ_∂ forms a group, and implies that κ forms a group. We define a serial family as one which is transitive and has connexity, *i.e.* we put

$$FM\,\text{sr} = FM\,\text{trs} \cap FM\,\text{connex} \quad \text{Df.}$$

Then if $\kappa \in FM\,\text{sr}$, $\dot{s}\text{`}\kappa_\partial$ is a serial relation, so that the points of the field of κ are arranged in a series by means of relations of distance.

When a family is serial, the vectors also can be arranged in a series, by means of a relation which may be regarded as that of greater and less. After a short number on initial families (explained above), we proceed to the consideration of greater and less (as it may be called) among vectors. We may call a point y "earlier" than a point z when there is a non-null vector which goes from y to z, *i.e.* when $z\,(\dot{s}\text{`}\kappa_\partial)\,y$. If $M, N \in \kappa_\iota$, we then say that N is "less" than M if the N-step from some point x takes us to an earlier point than the M-step. Writing V_κ for "greater than" among members of κ_ι, our definition is

$$V_\kappa = \hat{M}\hat{N}\{M, N \in \kappa_\iota : (\exists x) \,.\, (M\text{`}x)\,(\dot{s}\text{`}\kappa_\partial)\,(N\text{`}x)\} \quad \text{Df.}$$

For the same relation confined to members of κ, we use the notation U_κ; thus

$$U_\kappa = V_\kappa \upharpoonright \kappa \quad \text{Df.}$$

If $\kappa \in FM\,\text{conx}$, we have

$$U_\kappa = \hat{P}\hat{Q}\{P, Q \in \kappa : (\exists T) \,.\, T \in \kappa_\partial \,.\, P = T \,|\, Q\};$$

this is generally the most serviceable formula for U_κ.

If κ is a serial family, U_κ and V_κ are series; and if κ is an initial family, U_κ is similar to $\dot{s}\text{`}\kappa_\partial$.

The last number in this Section is concerned with the axiom of Archimedes and with the existence of sub-multiples of vectors. The axiom of Archimedes will be expressed by saying that if a is any member of the

field of κ, and R is any vector, then $R^{\nu}{}^{\backprime}a$, for a sufficiently great finite ν, will be later than any assigned member of the field of κ. In other words, putting $P = \mathrm{Cnv}{}^{\backprime}\dot{s}{}^{\backprime}\kappa_\partial$, we wish to have

$$x \in C{}^{\backprime}P \,.\, \supset_x .\, (\exists \nu) \,.\, \nu \in \mathrm{NC\,ind} - \iota{}^{\backprime}0 \,.\, xP(R^{\nu}{}^{\backprime}a),$$

or, what comes to the same thing,

$$P{}^{\backprime\backprime}\overrightarrow{R_*}{}^{\backprime}a = C{}^{\backprime}P.$$

This will hold if κ is a serial family and P is semi-Dedekindian (cf. $*214$). If, further, P is compact (*i.e.* $P^2 = P$), then all finite sub-multiples of a given vector exist, *i.e.*

$$S \in \kappa \,.\, \nu \in \mathrm{NC\,ind} - \iota{}^{\backprime}0 \,.\, \supset .\, (\exists L) \,.\, L \in \kappa \,.\, S = L^{\nu}.$$

It will be observed that, according to our definition of ratio, if $S = L^{\nu}$ and $S \neq \dot{\Lambda}$, L has to S the ratio $1/\nu$, so that L is the νth sub-multiple of S.

Instead of treating vector-families by the method we have adopted, we might have started from a double descriptive function, which we may denote by $x + y$, and concerning which we should make various hypotheses. By the general notation of $*38$, we obtain various relations of the form $+\,y$ or $x\,+$. These relations may replace the κ employed in our method. For convenience of notation, we may put

$$\overrightarrow{+}{}^{\backprime}y = +\,y \quad \mathrm{Df},$$

$$\overleftarrow{+}{}^{\backprime}x = x\,+ \quad \mathrm{Df}.$$

Then if $+$ has suitable properties, and γ is a suitable class, $\overrightarrow{+}{}^{\backprime\backprime}\gamma$ will be a vector family.

Let us assume that $x + y$ exists when, and only when, x and y both belong to the class γ, and that when x and y both belong to the class γ, $x + y$ also belongs to this class. Then if $x + y$ exists, so does $x + y + y$; hence $\mathrm{D}{}^{\backprime}+y \subset \mathrm{Cl}{}^{\backprime}+y$. Further, by our assumptions, if $x, y \in \gamma$, $x + y$ exists, and therefore $x \in \mathrm{Cl}{}^{\backprime}+y$. Hence $y \in \gamma \,.\, \supset .\, \mathrm{Cl}{}^{\backprime}+y = \gamma$. Hence if γ exists,

$$\mathrm{Cl}{}^{\backprime\backprime}\overrightarrow{+}{}^{\backprime\backprime}\gamma \in 1 \,.\, s{}^{\backprime}\mathrm{D}{}^{\backprime\backprime}\overrightarrow{+}{}^{\backprime\backprime}\gamma \subset s{}^{\backprime}\mathrm{Cl}{}^{\backprime\backprime}\overrightarrow{+}{}^{\backprime\backprime}\gamma.$$

If we now assume $\quad y + x = z + x \,.\, \supset_{x,y,z} .\, y = z,$

then $\overrightarrow{+}{}^{\backprime\backprime}\gamma \subset 1 \rightarrow 1$. Hence we now have

$$\overrightarrow{+}{}^{\backprime\backprime}\gamma \in \mathrm{Cl\ ex}{}^{\backprime}\mathrm{cr}{}^{\backprime}\gamma.$$

In order to obtain the Abelian property, we require

$$(x + y) + z = (x + z) + y,$$

which holds if $+$ obeys the permutative and associative laws. Thus in this case,

$$\overrightarrow{+}{}^{\backprime\backprime}\gamma \in \mathrm{fm}{}^{\backprime}\gamma.$$

In order that $\overrightarrow{+}{}^{\text{``}}\gamma$ may be a *connected* family, we require

$$(\exists a) :. z \,\epsilon\, \gamma \,.\, \supset_z : (\exists y) : a = z + y \,.\, \vee \,.\, z = a + y.$$

A sufficient, though not a necessary, condition for this is that there should be a zero, *i.e.*

$$(\exists a) : z \,\epsilon\, \gamma \,.\, \supset_z \,.\, z = a + z.$$

In this case, $+a$ is the zero vector, and if a is not the sum of two terms other than itself, a is the initial point of the family.

The condition that if x, y are members of γ so is $x + y$ secures that $\overrightarrow{+}{}^{\text{``}}\gamma$ is a group. Families which are groups we denote by "FM grp."

Thus collecting what has been said, we find that

$$\overrightarrow{+}{}^{\text{``}}\gamma \,\epsilon\, FM \,\text{conx grp}$$

if $+$ fulfils the following conditions:

(1) $x + y$ exists when, and only when, $x, y \,\epsilon\, \gamma$;

(2) $x, y \,\epsilon\, \gamma \,.\, \supset_{x,y} \,.\, x + y \,\epsilon\, \gamma$;

(3) $x + y = x + z \,.\, \supset_{x,y,z} \,.\, y = z$;

(4) $x + y = y + x$;

(5) $(x + y) + z = x + (y + z)$;

(6) $(\exists a) : z \,\epsilon\, \gamma \,.\, \supset_z \,.\, z = a + z$.

From (3) and (4) it follows that the a of (6) is unique, *i.e.* there cannot be more than one zero.

In order to insure that our family shall have connexity, we require further

(7) $x, y \,\epsilon\, \gamma \,.\, \supset_{x,y} : (\exists z) : z \,\epsilon\, \gamma : x + z = y \,.\, \vee \,.\, y + z = x$;

(8) in order that our family may be an initial family we require that $x + y$ shall only be zero when x and y are zero.

With this further condition, our family becomes serial.

The above is only a sketch of one of the simplest ways of generating families by means of double descriptive functions. Other ways are possible, and by greater complication greater generality can be obtained.

There are some advantages in the above manner of treatment. First, it is possible to take our magnitudes as being the x and y which appear in "$x + y$," instead of having to take them as the vectors $+y$ or $x+$. Secondly, our vector-family derives unity from the fact of being generated by the single operation $+$. Thirdly, the method is more in agreement with current conceptions of quantity than the method we have adopted. The choice

between the two methods is a matter of taste; but it would seem that the method we have adopted is capable of somewhat greater generality than the other, and that it requires less new technical apparatus than the other. We have not elsewhere had occasion to treat of double descriptive functions which only exist when their arguments belong to assigned classes, though it is to be observed that our definitions of various kinds of addition and multiplication might quite easily have been so framed as to give this result. For instance, we might have put

$$\mu +_0 \nu = (\imath \varpi) \{(\exists \alpha, \beta) \,.\, \mu = N_0 c\text{'}\alpha \,.\, \nu = N_0 c\text{'}\beta \,.\, \varpi = Nc\text{'}(\alpha + \beta)\} \quad \text{Df.}$$

In that case, $E ! (\mu +_0 \nu)$ would have implied $\mu, \nu \in N_0C$, whereas with our definition it is only $\exists ! (\mu +_0 \nu)$ that implies $\mu, \nu \in N_0C$. The general treatment of double functions which only exist in certain cases would require a considerable logical apparatus not required elsewhere in our work, and this is, for us, a reason against adopting the method of treating vector-families which derives them, as in the above sketch, from a single function $x + y$.

*330. ELEMENTARY PROPERTIES OF VECTOR-FAMILIES.

Summary of *330

In this number, we begin by defining the class of "correspondences" of α. A "correspondence" of α is a one-one relation R which makes every member of α correspond to an α, *i.e.* which is such that, if $x \epsilon \alpha$, $R‘x$ always exists and is a member of α. Thus, for example, if μ is an inductive number, $+_0 \mu$, with its field limited to inductive numbers, is a correspondence of the class of inductive numbers, provided the axiom of infinity holds. (Otherwise, $(+_0 \mu) \upharpoonright$ NC induct is not one-one.) The definition of correspondences of α is

*330·01. $\mathrm{cr}‘\alpha = (1 \rightarrow 1) \cap \overleftarrow{\mathrm{G}}‘\alpha \cap \breve{\mathrm{D}}‘‘\mathrm{Cl}‘\alpha$ Df

I.e. a correspondence of α is a one-one relation whose converse domain is α and whose domain is contained in α. The definition should be compared with the definition of "cror‘P" in *208.

It will be seen that if $R \epsilon \mathrm{cr}‘\alpha$ and $x \epsilon \alpha$, $R‘x$ exists and is an α, and therefore $R‘R‘x$ exists and is an α, and so on. Hence all the powers of R exist (*330·23). Similarly if $R, S, T, \ldots$ are any finite number of correspondences of α, $R \mid S \mid T \mid \ldots$ exists. This is proved for two and three factors in *330·21·22.

We define a "vector-family of α" as an existent Abelian class of correspondences of α, where an Abelian class of relations is defined as one such that the relative product of any two of its members is commutative. Thus we put

*330·02. $\mathrm{Abel} = \hat{\kappa}(R, S \epsilon \kappa \,.\, \supset_{R,S} \,.\, R \mid S = S \mid R)$ Df

*330·03. $\mathrm{fm}‘\alpha = \mathrm{Abel} \cap \mathrm{Cl\,ex}‘\mathrm{cr}‘\alpha$ Df

*330·04. $FM = s‘\mathrm{D}‘\mathrm{fm}$ Df

It will be remembered that Potid‘P and (for certain kinds of relations) finid‘P are Abelian classes of relations (*91·34 and *121·352). If $P \epsilon 1 \rightarrow 1$, Potid‘$P$ will be a vector-family of $C‘P$, and if further $P_{\mathrm{po}} \subseteq J$, finid‘$P$ will be the same vector-family.

One other definition belongs to this number, namely

*330·05. $\kappa_\iota = s‘(\mathrm{Cnv}‘‘\kappa) \,\big|_{,,}‘‘\kappa$ Df

This definition has been sufficiently discussed in the summary of the present Section.

After some preliminary propositions on Cl ex‘cr‘α (*330·1—·32) and on κ_ι (*330·4—·43), we proceed to such properties of families as do not require any further hypothesis as to the nature of the family concerned. These properties are mainly such as assert the existence of relative products, and of logical products of converse domains, or such as assert commutativeness of the relative product under certain circumstances. The earlier propositions deal with members of κ, the later propositions mainly with members of κ_ι. The most useful propositions are:

*331. CONNECTED FAMILIES.

Summary of *331.

A "connected point" of a family κ is a point of the field of κ from which every member of the field can be reached by a member of κ or the converse of a member. That is, if a is a connected point, we are to have

$$x \in s`\text{Ɑ}``\kappa \,.\supset_x .\, (\exists R) \,.\, R \in \kappa \,.\, x(R \cup \breve{R})\, a$$

as well as $a \in s`\text{Ɑ}``\kappa$. This amounts to saying that every member of $s`\text{Ɑ}``\kappa$ is of the form $R`a$ or $\breve{R}`a$, where $R \in \kappa$. The definition is

***331·01.** $\mathrm{conx}`\kappa = s`\text{Ɑ}``\kappa \cap \hat{a}\,(\overrightarrow{\dot{s}`\kappa}`a \cup \overleftarrow{\dot{s}`\kappa}`a = s`\text{Ɑ}``\kappa)$ Df

Here we include the factor $s`\text{Ɑ}``\kappa$ in the definition, in order to exclude the case when $\kappa = \iota`\dot{\Lambda}$. If $s`\text{Ɑ}``\kappa$ were not included, we should have $\mathrm{conx}`\iota`\dot{\Lambda} = \mathrm{V}$, whereas with the above definition $\mathrm{conx}`\iota`\dot{\Lambda} = \Lambda$.

In the case of any other family, the factor $s`\text{Ɑ}``\kappa$ makes no difference, since if $s`\text{Ɑ}``\kappa$ exists,

$$\overrightarrow{\dot{s}`\kappa}`a \cup \overleftarrow{\dot{s}`\kappa}`a = s`\text{Ɑ}``\kappa \,.\supset .\, a \in C`\dot{s}`\kappa,$$

and if κ is a family, $C`\dot{s}`\kappa = s`\text{Ɑ}``\kappa$. But in the case of $\iota`\dot{\Lambda}$, the factor $s`\text{Ɑ}``\kappa$ insures that no connected point exists, thus securing, conversely, that a family which has a connected point is not $\iota`\dot{\Lambda}$. This is convenient since the case of $\iota`\dot{\Lambda}$, which is trivial, would often otherwise have to be explicitly excluded.

The definition would be more analogous to the definition of a connected relation in *202 if we put

$$\mathrm{conx}`\kappa = s`\text{Ɑ}``\kappa \cap \hat{a}\,(\overrightarrow{\dot{s}`\kappa_\partial}`a \cup \overleftarrow{\dot{s}`\kappa_\partial}`a \cup \iota`a = s`\text{Ɑ}``\kappa) \quad \text{Df.}$$

But this definition fails to give us the information that there is a member of κ which relates a to itself, whereas our definition does give this information, and hence leads to the proof that $I \upharpoonright s`\text{Ɑ}``\kappa \in \kappa$, *i.e.* that there is a zero vector.

We say that a family "is connected" when it has at least one connected point, *i.e.* we put

***331·02.** $FM\,\mathrm{conx} = FM \cap \hat{\kappa}\,(\exists\,!\,\mathrm{conx}`\kappa)$ Df

When *all* points of the field are connected points, the family "has connexity" (cf. $*334\cdot27$), provided $\kappa \neq \iota`\Lambda$. For the present, we only assume that at least one of the points of the field is a connected point. To take an illustration: the family whose members are of the form $(\times_0 \mu) \upharpoonright (\text{NC induct} - \iota`0)$, where $\mu \in \text{NC induct} - \iota`0$, has only one connected point, namely 1. If we had taken positive and negative integers, both as multipliers and as constituting the field, we should have had two connected points, namely 1 and -1.

Almost all our future propositions on vector-families will be confined to *connected* families. In the present number, we prove first that in a connected family κ, the vector which relates a connected point to itself also relates any other member of the field to itself ($*331\cdot2$), whence it follows that $I \upharpoonright s`\text{C}``\kappa$ is a member of $\kappa$ ($*331\cdot22$), and that every other member of $\kappa$ is wholly contained in diversity ($*331\cdot23$), and that $\kappa \cup \text{Cnv}``\kappa \subset \kappa_\iota$ ($*331\cdot24$). We next prove that the product of two members of κ is a member of κ or of $\text{Cnv}``\kappa$ ($*331\cdot33$). We then proceed to consider $\kappa_\iota$, and prove at once the two fundamental properties of $\kappa_\iota$ in a connected family, namely (1) that between any two members of $s`\text{C}``\kappa$ there is a relation which is a member of κ_ι ($*331\cdot4$), and (2) that two members of κ_ι whose logical product exists are identical ($*331\cdot42$). From these two propositions it follows that there is just one member of κ_ι which relates any two members of $s`\text{C}``\kappa$ ($*331\cdot43$). Finally we prove that any power of a member of $\kappa$ is a member of $\kappa \cup \text{Cnv}``\kappa$ ($*331\cdot54$), and that any power of a member of κ_ι is contained in some member of κ_ι ($*331\cdot56$).

Stated symbolically, the above propositions are as follows:

$*332$. ON THE REPRESENTATIVE OF A RELATION IN A FAMILY.

Summary of $*332$.

We saw at the end of the last number ($*331\cdot56$) that any power of a member of κ_ι is contained in a member of κ_ι. When a relation is contained in a member of κ_ι, we call this member the "representative" of the relation in the family. For purposes connected with the application of ratio, the "representative" is an important function of a relation, especially when the relation concerned is a power of a member of κ_ι. By the definition of ratio ($*303\cdot01$), we shall have $L(\rho/\sigma)M$ if $\dot{\exists} ! L^\sigma \dot{\land} M^\rho$ and $\rho \operatorname{Prm} \sigma$. Now if L^σ and M^ρ each have a representative, then they must have the *same* representative if $\dot{\exists} ! L^\sigma \dot{\land} M^\rho$ (by $*331\cdot42$). Hence we are enabled to substitute an equality for $\dot{\exists} ! L^\sigma \dot{\land} M^\rho$ in dealing with ratios of members of κ_ι. The elementary properties of representatives are dealt with in the present number.

We denote the representative of P in the family κ by "$\operatorname{rep}_\kappa{}^\backprime P$." In order to insure $\mathrm{E} ! \operatorname{rep}_\kappa{}^\backprime P$ under all circumstances, we do not define $\operatorname{rep}_\kappa{}^\backprime P$ as the only member of κ_ι which contains P, but as the logical sum of the class of members of κ_ι which contain P, *i.e.* we put

$*332\cdot01$. $\operatorname{rep}_\kappa{}^\backprime P = \dot{s}{}^\backprime(\kappa_\iota \cap \overleftarrow{\mathrm{G}}{}^\backprime P)$ Df

In a connected family, if P is not null, $\kappa_\iota \cap \overleftarrow{\mathrm{G}}{}^\backprime P$ cannot have more than one member ($*332\cdot21$), and therefore the representative of P, if it is not null, must be a member of κ_ι ($*332\cdot22$). If P is a member of κ_ι, it is its own representative ($*332\cdot241$).

We prove in this number that, if $P, Q, R, \ldots$ have existent representatives, the representative of their relative product (unless this product is null) is the representative of the relative product of their representatives ($*332\cdot37$). Among other important propositions in this number are the following:

$*332\cdot32$. $\vdash : \kappa \in FM \operatorname{conx} . L, M \in \kappa_\iota . \supset . \operatorname{rep}_\kappa{}^\backprime(L \mid M) = \operatorname{rep}_\kappa{}^\backprime(M \mid L)$

*333. OPEN FAMILIES.

Summary of *333.

An "open" family is defined as one such that, if L is any member of κ_ι which is not contained in identity, then every power of L is contained in diversity, *i.e.* $L_{\text{po}} \subset J$. We shall often have occasion, both in this number and later, to consider the class $\kappa_\iota - \text{Rl}`I$, and in later numbers we shall often have occasion to consider the class $\kappa - \text{Rl}`I$. We therefore put

***333·01.** $\kappa_\partial = \kappa - \text{Rl}`I$ Df

***333·011.** $\kappa_{\iota\partial} = (\kappa_\iota)_\partial$ Df

Thus $\kappa_{\iota\partial}$ consists of all members of κ_ι which are not contained in identity, *i.e.* (if κ is a connected family) all members of κ_ι except $I \upharpoonright s`\text{C}``\kappa$. The definition of an "open" family is

***333·02.** $FM\,\text{ap} = FM \cap \hat{\kappa}\,\{s`\text{Pot}``\kappa_{\iota\partial} \subset \text{Rl}`J\}$ Df

From the point of view of the application of ratio, the hypothesis that a family is open is very important. To begin with, it insures (*333·18) that $\kappa_{\iota\partial}$ consists of "numerical" relations (cf. *300), so that if $L \in \kappa_{\iota\partial}$, we have $\text{Pot}`L = \text{fin}`L$ (*333·15), and in virtue of *300·491, the existence of open families implies the axiom of infinity (*333·19).

Again, in an open connected family, if L, M are two different members of κ_ι, all the powers of $L \,|\, \breve{M}$ are contained in diversity, and therefore the representatives of these powers are members of $\kappa_{\iota\partial}$; that is, we have

***333·22.** $\vdash : \kappa \in FM\,\text{ap}\,\text{conx} \,.\, L, M \in \kappa_\iota \,.\, L \neq M \,.\, \supset .\, \text{rep}_\kappa``\text{Pot}`(L \,|\, \breve{M}) \subset \kappa_{\iota\partial}$

It follows from this proposition that, with the above hypothesis, if σ is any inductive cardinal other than 0, $L^\sigma \,|\, \breve{M}^\sigma$ is not contained in identity, and therefore $L^\sigma \neq M^\sigma$ and $\text{rep}_\kappa`L^\sigma \neq \text{rep}_\kappa`M^\sigma$. Hence by transposition we obtain the two propositions:

***333·41.** $\vdash :.\, \kappa \in FM\,\text{ap}\,\text{conx} \,.\, L, M \in \kappa_\iota \,.\, \sigma \in \text{NC ind} - \iota`0 \,.\, \supset :$
$\text{rep}_\kappa`L^\sigma = \text{rep}_\kappa`M^\sigma \,.\, \equiv .\, L = M$

***333·42.** $\vdash :. \text{Hp} *333\cdot41 . \supset : L^\sigma = M^\sigma . \equiv . L = M$

Hence we obtain

***333·43.** $\vdash :. \text{Hp} *333\cdot41 . \supset : \dot{\exists} ! L^\sigma \dot{\frown} M^\sigma . \equiv . L = M$

This proposition shows that in an open connected family, no two members of κ_ι have the ratio 1/1 unless they are identical. Again it follows from *333·41 that if $L^{\rho \times_c \tau}$ and $M^{\sigma \times_c \tau}$ have the same representative, then L^ρ and M^σ have the same representative, and vice versa, *i.e.*

***333·44.** $\vdash :. \kappa \in FM \text{ ap conx} . L, M \in \kappa_\iota . \rho, \sigma, \tau \in \text{NC ind} - \iota'0 . \supset :$

$$\text{rep}_\kappa{}'L^{\rho \times_c \tau} = \text{rep}_\kappa{}'M^{\sigma \times_c \tau} . \equiv . \text{rep}_\kappa{}'L^\rho = \text{rep}_\kappa{}'M^\sigma$$

Hence we obtain two propositions which are vital for the application of ratio, namely:

***333·47.** $\vdash :. \kappa \in FM \text{ ap conx} . L, M \in \kappa_\iota . \rho, \sigma \in \text{NC ind} - \iota'0 . \supset :$

$$\text{rep}_\kappa{}'L^\rho = \text{rep}_\kappa{}'M^\sigma . \equiv . \dot{\exists} ! L^\rho \dot{\frown} M^\sigma$$

***333·48.** $\vdash :. \kappa \in FM \text{ ap conx} . L, M \in \kappa_\iota . \rho, \sigma, \tau \in \text{NC ind} - \iota'0 . \supset :$

$$\dot{\exists} ! L^\rho \dot{\frown} M^\sigma . \equiv . \dot{\exists} ! L^{\rho \times_c \tau} \dot{\frown} M^{\sigma \times_c \tau}$$

On comparing this last proposition with the definition of ratio (*303·01), it will be seen that, whether ρ is prime to σ or not, L has to M the ratio σ/ρ when, and only when, $\dot{\exists} ! L^\rho \dot{\frown} M^\sigma$, *i.e.* (by *333·47) when, and only when, $\text{rep}_\kappa{}'L^\rho = \text{rep}_\kappa{}'M^\sigma$.

From *333·47 it follows also that, if $M \in \kappa_{\iota\partial}$, M^ρ and M^σ will not have the same representative unless $\rho = \sigma$ (*333·51), *i.e.*

***333·51.** $\vdash :. \kappa \in FM \text{ ap conx} . M \in \kappa_{\iota\partial} . \rho, \sigma \in \text{NC ind} . \supset :$

$$\text{rep}_\kappa{}'M^\rho = \text{rep}_\kappa{}'M^\sigma . \equiv . \rho = \sigma$$

From this it follows that no member of $\kappa_{\iota\partial}$ has any other ratio to itself than 1/1. Again, by *333·47·48·51, we have

***333·53.** $\vdash : \kappa \in FM \text{ ap conx} . L, M \in \kappa_{\iota\partial} . \dot{\exists} ! L^\sigma \dot{\frown} M^\rho . \dot{\exists} ! L^\nu \dot{\frown} M^\mu . \supset .$

$$\mu \times_0 \sigma = \nu \times_0 \rho$$

Hence if L and M have the two ratios ρ/σ, μ/ν, we have $\rho/\sigma = \mu/\nu$; that is, no two members of $\kappa_{\iota\partial}$ have more than one ratio.

The applications of ratio indicated in this summary will not be made till the following Section; they are here mentioned in order to show the utility of the propositions of the present number.

***333·01.** $\kappa_\partial = \kappa - \text{Rl}'I$ Df

***333·011.** $\kappa_{\iota\partial} = (\kappa_\iota)_\partial$ Df

***333·02.** $FM \text{ ap} = FM \cap \hat{\kappa} \{s'\text{Pot}``\kappa_{\iota\partial} \subset \text{Rl}'J\}$ Df

***333·03.** $FM \text{ ap conx} = FM \text{ ap} \cap FM \text{ conx}$ Df

*334. SERIAL FAMILIES.

Summary of *334.

The purpose of the present number is to consider what properties of a family κ will insure that $\dot{s}`\kappa_\partial$ is serial, or has one or more of the properties characteristic of serial relations. Suppose, for example, that κ consists of distances on a line. Then κ_∂ consists of those distances which are members of κ and are not zero. Any selection of distances on the line may constitute κ; thus *e.g.* κ may consist of all distances which are integral multiples of a given distance, or of all which are rational multiples of a given distance, or of all distances from left to right, or of all distances on the line in either direction. It is plain to begin with that if $\dot{s}`\kappa_\partial$ is to be serial, $\kappa$ must not contain equal distances in opposite directions, since if it does, $(\dot{s}`\kappa_\partial)^2$ will not be contained in diversity, *i.e.* $\dot{s}`\kappa_\partial$ will not be asymmetrical We call a family κ asymmetrical when no member of κ_∂ has a converse which is also a member of κ_∂. The definition is

***334·05.** $FM\,\mathrm{asym} = FM \cap \hat{\kappa}(\kappa \cap \mathrm{Cnv}``\kappa \subset \mathrm{Rl}`I)$ Df

It will be observed that $\dot{s}`\kappa_\partial \in J$ in any connected family, by *331·23. If $\kappa \in FM\,\mathrm{asym}$, we have also $(\dot{s}`\kappa_\partial)^2 \in J$.

In order to secure that $\dot{s}`\kappa_\partial$ shall be *transitive*, we require that the field of κ should contain at least one "transitive point," where a "transitive point" means a point a such that any point which can be reached from a by two successive non-zero steps can also be reached by one non-zero step, *i.e.* such that

$$(\dot{s}`\kappa_\partial)``\overrightarrow{\dot{s}`\kappa_\partial}`a \subset \overrightarrow{\dot{s}`\kappa_\partial}`a.$$

The definition of transitive points is

***334·01.** $\mathrm{trs}`\kappa = s`\mathrm{C}``\kappa \cap \hat{a}\{(\dot{s}`\kappa_\partial)``\overrightarrow{\dot{s}`\kappa_\partial}`a \subset \overrightarrow{\dot{s}`\kappa_\partial}`a\}$ Df

Thus if a is a transitive point, and $R, S \in \kappa_\partial$, there is always a member of κ_∂, say T, such that $R`S`a = T`a$. It will be seen that if κ is a connected family, the existence of a transitive point implies that the family is asymmetrical. Again, if there is a transitive point in a connected family, then $R, S \in \kappa_\partial . \supset . R | S \in \kappa_\partial$, by *331·32; hence κ_∂ is a group. The converse also

holds, *i.e.* if κ_∂ is a group, any member $s'\text{Ɑ}''\kappa$ is a transitive point (*334·11). Hence if there is any transitive point, every point of $s'\text{Ɑ}''\kappa$ is a transitive point.

The definition of a transitive family is

***334·02.** $FM\,\mathrm{trs} = FM \cap \hat{\kappa}\,(\exists !\,\mathrm{trs}'\kappa)$ Df

By what has just been said, a connected transitive family is one in which κ_∂ is a group, *i.e.*

***334·13.** $\vdash :.\ \kappa \in FM\,\mathrm{conx}\,.\supset :\kappa \in FM\,\mathrm{trs}\,.\equiv .\, s'\kappa_\partial \underset{\prime\prime}{|}{}''\kappa_\partial \subset \kappa_\partial$

A connected family is transitive when, and only when, $\dot{s}'\kappa_\partial$ is a transitive relation, *i.e.*

***334·14.** $\vdash :.\ \kappa \in FM\,\mathrm{conx}\,.\supset :\kappa \in FM\,\mathrm{trs}\,.\equiv .\,\dot{s}'\kappa_\partial \in \mathrm{trans}$

In order to secure that $\dot{s}'\kappa_\partial$ shall be a *connected* relation, it is not enough that κ should be an FM conx, *i.e.* that $s'\text{Ɑ}''\kappa$ should have at least one connected point. We require that *every* point of $s'\text{Ɑ}''\kappa$ should be a connected point. This will be secured if there is a connected point which belongs to the field of every member of κ_ι, *i.e.* if

$$\exists !\,\mathrm{conx}'\kappa \cap p'C''\kappa_\iota .$$

For suppose $a \in \mathrm{conx}'\kappa \cap p'C''\kappa_\iota$. Then if $L \in \kappa_\iota$, either $L'a$ or $\breve{L}'a$ exists, and is of the form $R'a$ or $\breve{R}'a$, where $R \in \kappa$. Hence, by *331·32, L is identical with R or with $\breve{R}$; hence $\kappa_\iota = \kappa \cup \mathrm{Cnv}''\kappa$. Hence by *331·4, $\dot{s}'\kappa_\partial \in$ connex. Conversely, if $\kappa \in FM\,\mathrm{conx}$ and $\dot{s}'\kappa_\partial \in \mathrm{connex}$, it follows from *331·32 that $\kappa_\iota = \kappa \cup \mathrm{Cnv}''\kappa$; hence $p'C''\kappa_\iota = s'\text{Ɑ}''\kappa$, and therefore we have $\exists !\,\mathrm{conx}'\kappa \cap p'C''\kappa_\iota$. Hence putting

***334·03.** $FM\,\mathrm{connex} = FM \cap \hat{\kappa}\,(\exists !\,\mathrm{conx}'\kappa \cap p'C''\kappa_\iota)$ Df

where "FM connex" means "families having connexity," we have

***334·26.** $\vdash :.\ \kappa \in FM\,\mathrm{conx}\,.\supset :\kappa \in FM\,\mathrm{connex}\,.\equiv .\,\dot{s}'\kappa_\partial \in \mathrm{connex}\,.$
$$\equiv .\,\kappa_\iota = \kappa \cup \mathrm{Cnv}''\kappa\,.\equiv .\,C''\kappa_\iota = \text{Ɑ}''\kappa$$

and

***334·27.** $\vdash .\ FM\,\mathrm{connex} = FM \cap \hat{\kappa}\,(s'\text{Ɑ}''\kappa = \mathrm{conx}'\kappa\,.\,\kappa \neq \iota'\dot{\Lambda})$

I.e. a family having connexity is one whose field consists wholly of connected points and is not null.

We thus secure (1) $\dot{s}'\kappa_\partial \mathrel{\dot{\subset}} J$ by the hypothesis $\kappa \in FM\,\mathrm{conx}$, (2) $\dot{s}'\kappa_\partial \in \mathrm{trans}$ by the hypothesis $\kappa \in FM\,\mathrm{conx} \cap FM\,\mathrm{trs}$, (3) $\dot{s}'\kappa_\partial \in \mathrm{connex}$ by the hypothesis $\kappa \in FM\,\mathrm{connex}$ (which implies $\kappa \in FM\,\mathrm{conx}$). Hence we secure $\dot{s}'\kappa_\partial \in \mathrm{Ser}$ by the hypothesis $\kappa \in FM\,\mathrm{trs} \cap FM\,\mathrm{connex}$. When this hypothesis is fulfilled, we call κ a "serial" family; thus we put

***334·04.** $FM \,\mathrm{sr} = FM \,\mathrm{trs} \cap FM \,\mathrm{connex}$ Df

and we have

***334·3.** $\vdash : \kappa \in FM \,\mathrm{sr} . \supset . \dot{s}`\kappa_\partial \in \mathrm{Ser}$

***334·31.** $\vdash :. \kappa \in FM . I \upharpoonright s`\mathrm{G}``\kappa \in \kappa . \supset : \kappa \in FM \,\mathrm{sr} . \equiv . \dot{s}`\kappa_\partial \in \mathrm{Ser} - \iota`\dot{\Lambda}$

An important special case, which is briefly considered in this number, is the case when the domains of members of κ are the same as their converse domains, *i.e.* when

$$\mathrm{D}``\kappa = \mathrm{G}``\kappa.$$

This case is illustrated, *e.g.* by the family whose members are all relations of the form $(+_g X) \upharpoonright C`H_g$, where $X \in C`H'$. It is also illustrated by cyclic families, which are considered in the next Section but one. When $\mathrm{D}``\kappa = \mathrm{G}``\kappa$, if κ is a family, so is $\kappa \cup \mathrm{Cnv}``\kappa$ (*334·4), and if $\kappa$ is a connected family, so is $\kappa \cup \mathrm{Cnv}``\kappa$ (*334·41). In the case of the above family, whose members are $(+_g X) \upharpoonright C`H_g$ where $X \in C`H'$, $\kappa \cup \mathrm{Cnv}``\kappa$ will consist of all relations $(+_g X) \upharpoonright C`H_g$ where $X \in C`H_g$, *i.e.* it will consist of all additions of positive or negative ratios to positive or negative ratios.

A connected family in which $\mathrm{D}``\kappa = \mathrm{G}``\kappa$ is a family having connexity, *i.e.*

***334·42.** $\vdash : \kappa \in FM \,\mathrm{conx} . \mathrm{D}``\kappa = \mathrm{G}``\kappa . \supset . \kappa \in FM \,\mathrm{connex}$

The definitions and propositions of this number are much used throughout the remainder of Part VI.

***334·01.** $\mathrm{trs}`\kappa = s`\mathrm{G}``\kappa \cap \hat{a} \{(\dot{s}`\kappa_\partial)``\overrightarrow{\dot{s}`\kappa_\partial}`a \subset \overrightarrow{\dot{s}`\kappa_\partial}`a\}$ Df

*335. INITIAL FAMILIES.

Summary of *335.

A family of vectors may or may not have a point in its field which is a starting-point but not an end-point of non-zero vectors. For example, the family of which a member is $(+_s X) \upharpoonright C'H'$, where $X \in C'H'$, has such a point in its field, namely 0_q; but the family of which a member is $(+_s X) \upharpoonright C'H$, where $X \in C'H'$, has no such point in its field, and no more has the family of which a member is $(+_g X) \upharpoonright C'H_g$, where $X \in C'H'$. If such a point exists, it is a member of $s'\text{Ꭰ}''\kappa$ but not of $s'\text{D}''\kappa_\partial$. Such a point, if it is also a connected point, must be unique, *i.e.* we have

***335·12.** $\vdash : \kappa \in FM . \supset . \text{conx}'\kappa - s'\text{D}''\kappa_\partial \in 0 \cup 1$

When $\text{conx}'\kappa - s'\text{D}''\kappa_\partial$ exists, we call its only member "the initial point of κ," putting

***335·01.** $\text{init}'\kappa = \breve{\iota}'(\text{conx}'\kappa - s'\text{D}''\kappa_\partial)$ Df

If the initial point of κ exists, we call κ an "initial" family; thus we put

***335·02.** $FM\,\text{init} = FM \cap \text{Ꭰ}'\text{init}$ Df

An initial family is asymmetrical (*335·16) and transitive (*335·18), and forms a group (*335·17); and if its initial point is a member of $p'C''\kappa_\iota$, it is a serial family (*335·3).

Summary of *336.

In this number we consider a relation between members of κ or of κ_ι which, with suitable limitations as to the nature of the family, may be identified with the relation of greater and less. If there is a member of κ which takes us from a point z to a point y, *i.e.* if $y (\dot{s}\text{‘}\kappa_\partial) z$, we say that z is an earlier point than y; thus we regard $\dot{s}\text{‘}\kappa_\partial$ as the relation of later to earlier. If now M and N are two members of κ_ι, and if, for some x, $M\text{‘}x$ is later than $N\text{‘}x$, we shall say that M is "greater" than N with respect to κ. This relation we denote by V_κ, where "V" is intended to suggest that the relation holds between *vectors*. The definition is:

***336·01.** $V_\kappa = \hat{M}\hat{N} \{M, N \epsilon \kappa_\iota : (\exists x) . (M\text{‘}x) (\dot{s}\text{‘}\kappa_\partial) (N\text{‘}x)\}$ Df

For the same relation when confined to members of κ, we use the notation U_κ; thus we put

***336·011.** $U_\kappa = V_\kappa \upharpoonright\!\!\upharpoonleft \kappa$ Df

In dealing with V_κ and U_κ it is desirable to be able to express $M\text{‘}x$ as a function of M. We wish to consider (say) a fixed origin a, and the various points $R\text{‘}a$, $S\text{‘}a$, $T\text{‘}a$, ... to which the various vectors which are members of κ carry us from a. For this purpose we put

$$R\text{‘}a = A_a\text{‘}R,$$

where "A" stands for "argument," and "$A_a\text{‘}R$" may be read "the value, for the argument a, of R." The definition is

$$A_a = \hat{x}\hat{R} (xRa) \quad \text{Df},$$

whence we obtain

***336·101.** $\vdash : E ! R\text{‘}a . \supset . R\text{‘}a = A_a\text{‘}R$

Then the points $R\text{‘}a, S\text{‘}a, T\text{‘}a, \ldots$, where $R, S, T, \ldots$ are the various members of κ, form the class $A_a\text{“}\kappa$, which is thus the same class as $\overrightarrow{\dot{s}\text{‘}\kappa}\text{‘}a$. The relation $A_a \upharpoonright \kappa$ correlates the point $R\text{‘}a$ with the vector R. The vector R is analogous to the coordinate of $R\text{‘}a$ when a is the origin; thus $A_a \upharpoonright \kappa$ is analogous to the relation of a point to its coordinate. A relation which is more exactly that of a point to its coordinate will be explained in Section C, where, in

addition to the above correlator $A_a \upharpoonright \kappa$, we shall also correlate a vector with its numerical measure in terms of an assigned unit.

If κ is a connected family, and a is any point of its field, $A_a \upharpoonright \kappa_\iota$ is a one-one relation (*336·2). If κ is an initial family, and a is its initial point, $A_a \upharpoonright \kappa$ is a correlator of $s`\mathrm{C}``\kappa$ and κ (*336·21), so that in an initial family the class of vectors is similar to the field (*336·22). If κ is a connected family, and a is any point of the field, and λ is those members L of κ_ι for which $L`a$ exists, then $A_a \upharpoonright \lambda$ correlates the field with λ, so that λ is similar to the field (*336·24).

By the definition of A_a, if $M \epsilon \kappa_\iota$ and $M`a$ exists, we have

$$M`a = A_a`M = A_a \upharpoonright \kappa_\iota`M.$$

Hence by the definition of V_κ,

$$\vdash : MV_\kappa N . \equiv . (\exists a) . (A_a \upharpoonright \kappa_\iota`M)(\dot{s}`\kappa_\partial)(A_a \upharpoonright \kappa_\iota`N) .$$

$$\equiv . (\exists a) . M(\kappa_\iota \upharpoonright \breve{A}_a ; \dot{s}`\kappa_\partial) N, \text{ by } *150{\cdot}41.$$

Similarly $\quad \vdash : PU_\kappa Q . \equiv . (\exists a) . P(\kappa \upharpoonright \breve{A}_a ; \dot{s}`\kappa_\partial) Q.$

Now in a connected family, if a and b are any two members of the field, and $P, Q \epsilon \kappa$,

$$(P`a)(\dot{s}`\kappa_\partial)(Q`a) . \equiv . (P`b)(\dot{s}`\kappa_\partial)(Q`b) \quad (*336{\cdot}38);$$

hence $$\kappa \upharpoonright \breve{A}_a ; \dot{s}`\kappa_\partial = \kappa \upharpoonright \breve{A}_b ; \dot{s}`\kappa_\partial,$$

and hence $$U_\kappa = \kappa \upharpoonright \breve{A}_a ; \dot{s}`\kappa_\partial \quad (*336{\cdot}43).$$

Since $\kappa \upharpoonright \breve{A}_a$ is one-one (by *336·2), the above gives an ordinal correlation of U_κ with $(\dot{s}`\kappa_\partial) \upharpoonright A_a``\kappa$ (*336·461), *i.e.* U_κ is ordinally similar to $\dot{s}`\kappa_\partial$ with its field confined to those points which can be reached from $a$ by vectors which are members of $\kappa$. If $\kappa$ is an initial family, it follows that $U_\kappa$ is similar to $\dot{s}`\kappa_\partial$ (*336·44); if not, U_κ is in general only similar to a segment of $\dot{s}`\kappa_\partial$ (in the sense of *213).

It should be observed that $\kappa_\iota \upharpoonright \breve{A}_a`x$ is the member of $\kappa_\iota$ which takes us from $a$ to $x$, and $\kappa \upharpoonright \breve{A}_a`x$ (if it exists) is the member of κ which takes us from a to x. Thus $\kappa \upharpoonright \breve{A}_a ; \dot{s}`\kappa_\partial$ is the series of vectors which take us from a to all the various points which can be reached from a by members of κ, the order of the series being that of the points to which the various vectors take us from a.

If κ is a connected family, U_κ is the relation which holds between two members of κ when one of them is the relative product of the other and a third (other than the zero vector), *i.e.*

***336·41.** $\vdash : \kappa \epsilon FM \,\mathrm{conx} . \supset . U_\kappa = \hat{P}\hat{Q}\{P, Q \epsilon \kappa : (\exists T) . T \epsilon \kappa_\partial . P = T \mid Q\}$

This is for many purposes the most convenient formula for U_κ. If, in addition, we have $\mathrm{D}``\kappa = \mathrm{Q}``\kappa$, a similar formula holds for V_κ, *i.e.*

***336·54.** $\vdash : \kappa \epsilon FM \,\mathrm{conx} \,.\, \mathrm{D}``\kappa = \mathrm{Q}``\kappa \,.\, \supset .$

$$V_\kappa = \hat{M}\hat{N}\{M, N \epsilon \kappa_\iota : (\exists T) \,.\, T \epsilon \kappa_\partial \,.\, M = T \mid N\}$$

If $\kappa \epsilon FM$ conx, V_κ is contained in diversity (*336·6); if κ is also transitive, V_κ is transitive (336·61); and if κ has connexity, so has V_κ (*336·62). Hence if κ is a serial family, V_κ and U_κ are serial (*336·63·64).

In addition to the above-mentioned propositions, the following propositions in this number are important:

***336·411.** $\vdash :. \kappa \epsilon FM \,\mathrm{conx} \,.\, s`\kappa \mid``\kappa \subset \kappa \,.\, \supset : PU_\kappa Q \,.\, R \epsilon \kappa \,.\, \supset . (P \mid R)\, U_\kappa (Q \mid R)$

***336·511.** $\vdash :. \kappa \epsilon FM \,\mathrm{sr} \,.\, \nu \epsilon \mathrm{NC\,ind} - \iota`0 \,.\, \supset : RU_\kappa S \,.\, \equiv .\, R^\nu U_\kappa S^\nu$

***336·53.** $\vdash :. \kappa \epsilon FM \,\mathrm{conx} \,.\, M, N \epsilon \kappa_\iota \,.\, \supset : MV_\kappa N \,.\, \equiv .\, \breve{N} V_\kappa \breve{M}$

The present number is important, since V_κ and U_κ are the general relations from which greater and less among magnitudes are derived, and the subject of magnitude is therefore intimately dependent upon them.

$*337$. MULTIPLES AND SUB-MULTIPLES OF VECTORS.

Summary of $*337$.

In this number, we are concerned with the axiom of Archimedes and the axiom of divisibility. If κ is a family of vectors, κ obeys the axiom of Archimedes if, given any two points x, a in the field of κ, and any vector R which is a member of κ, there is some power R^ν of R such that $R^{\nu}{}^{\text{\textquoteleft}}a$ is later than x. That is, κ obeys the axiom of Archimedes if, starting from any given point in the field, a sufficient finite number of repetitions of any given vector will take us beyond any other assigned point. A sufficient hypothesis for this is that κ should be serial and $\text{Cnv}{}^{\text{\textquoteleft}}\dot{s}{}^{\text{\textquoteleft}}\kappa_\partial$ should be semi-Dedekindian (cf. $*214$), *i.e.* we have

$$*337{\cdot}13. \quad \vdash :. \kappa \in FM\,\text{sr} . \breve{P} = \dot{s}{}^{\text{\textquoteleft}}\kappa_\partial . P \in \text{semi Ded} . R \in \kappa_\partial . a \in C{}^{\text{\textquoteleft}}P . \supset :$$
$$x \in C{}^{\text{\textquoteleft}}P . \supset . (\exists \nu) . \nu \in \text{NC ind} - \iota{}^{\text{\textquoteleft}}0 . xP(R^{\nu}{}^{\text{\textquoteleft}}a)$$

The hypothesis $\breve{P} = \dot{s}{}^{\text{\textquoteleft}}\kappa_\partial$, which appears in the above proposition, is often notationally convenient. It will be observed that $\dot{s}{}^{\text{\textquoteleft}}\kappa_\partial$ gives us the series in the opposite order to that in which it is usually wanted; hence the introduction of the above relation P tends to avoid confusions.

A family κ is said to obey the axiom of divisibility when, given any member R of κ, and any inductive cardinal ν other than 0, there is a member L of κ such that $L^\nu = R$. When this axiom holds, every vector can be divided into any assigned finite number of equal parts. We shall in the next Section ($*351$) define a family for which this holds as a "sub-multipliable family," denoted by "FM subm." For the present we are concerned to find a hypothesis as to $\dot{s}{}^{\text{\textquoteleft}}\kappa_\partial$ from which this property can be deduced. The hypothesis in question is that $\text{Cnv}{}^{\text{\textquoteleft}}\dot{s}{}^{\text{\textquoteleft}}\kappa_\partial$ is serial, compact, and semi-Dedekindian; *i.e.* we have

$$*337{\cdot}27. \quad \vdash :. \kappa \in FM\,\text{sr} . \text{Cnv}{}^{\text{\textquoteleft}}\dot{s}{}^{\text{\textquoteleft}}\kappa_\partial \in \text{comp} \cap \text{semi Ded} . \supset :$$
$$S \in \kappa . \nu \in \text{NC ind} - \iota{}^{\text{\textquoteleft}}0 . \supset . (\exists L) . L \in \kappa . S = L^\nu$$

The proof proceeds by taking two points a, x in the field of κ, of which a is earlier than x, and considering the class

$$\lambda = \kappa_\partial \cap \breve{R}\{(R^{\nu}{}^{\text{\textquoteleft}}a)\,Px\},$$

i.e. the class of vectors such that ν repetitions of them, starting from a, do not take us as far as x. It is easy to show that, when P is compact, this class has no maximum (*337·23), and therefore, when P is also semi-Dedekindian, has a limit, whose νth power is the vector which takes us from a to x (*337·26). Hence our result follows.

SECTION C.

MEASUREMENT.

Summary of Section C.

In this Section, the "pure" theory of ratios and real numbers developed in Section A is applied to vector-families. A vector-family, if it has suitable properties, may be regarded as a kind of magnitude. In order to derive from the "pure" theory of ratio a theory of measurement having the properties which we should expect, it is necessary to confine ourselves to some one vector-family; that is, instead of considering the general relation X, where X is a ratio, we consider the relation $X \upharpoonright \kappa$, where κ is the vector-family in question; or sometimes we consider $X \upharpoonright \kappa_\iota$, or sometimes $X \upharpoonright (\kappa \cup \mathrm{Cnv}``\kappa)$.

Concerning ratios with their fields thus limited, which are what we may call "applied" ratios, we have to prove various propositions.

(1) No two members of a family must have two different ratios. This is proved, for an open and connected family, in $*350{\cdot}44$.

(2) All ratios except 0_q and ∞_q must be one-one relations when limited to a single family. This is proved, for an open and connected family, in $*350{\cdot}5$; with the same hypothesis, 0_q is one-many ($*350{\cdot}51$).

(3) The relative product of two applied ratios ought to be equal to the arithmetical product of the corresponding pure ratios with its field limited, *i.e.* if X, Y are ratios, we ought to have

$$X \upharpoonright \kappa \mid Y \upharpoonright \kappa = (X \times_s Y) \upharpoonright \kappa$$

or

$$X \upharpoonright \kappa_\iota \mid Y \upharpoonright \kappa_\iota = (X \times_s Y) \upharpoonright \kappa_\iota .$$

That is to say, two-thirds of half a pound of cheese ought to be $(2/3 \times_s 1/2)$ of a pound of cheese; and similarly in any other case. For any open connected family, we have ($*350{\cdot}6$)

$$X \upharpoonright \kappa_\iota \mid Y \upharpoonright \kappa_\iota \subset (X \times_s Y) \upharpoonright \kappa_\iota ,$$

but in order to obtain an equation instead of an inclusion, it is necessary ($*351{\cdot}31$) that κ should be "submultipliable," *i.e.* that if R is any member of κ, and ν any inductive cardinal other than zero, there should be a member of κ whose νth power is R. The class of such families is denoted by "FM subm," and considered in $*351$.

(4) If X, Y are ratios and T is a member of the family κ, we ought to have

$$(X \underset{\cdot}{[} \kappa{}^{\backprime}T) \mid (Y \underset{\cdot}{[} \kappa{}^{\backprime}T) = (X +_s Y) \underset{\cdot}{[} \kappa{}^{\backprime}T,$$

that is, two-thirds of a pound of cheese together with half a pound of cheese ought to be $(2/3 +_s 1/2)$ of a pound of cheese, and similarly in any other instance. This property is shown, in $*351{\cdot}43$, to hold for any open connected submultipliable family in which all powers of members are members. In any open connected family, if $R, S, T \in \kappa$, we have

$$RXT \,.\, SYT \,.\, \supset . \,(R \mid S)(X +_s Y)\, T \quad (*350{\cdot}62).$$

The remainder of the hypothesis of $*351{\cdot}43$ is required in order to prove (a) that $X \underset{\cdot}{[} \kappa{}^{\backprime}T$, $Y \underset{\cdot}{[} \kappa{}^{\backprime}T$ and $(X +_s Y) \underset{\cdot}{[} \kappa{}^{\backprime}T$ exist, (b) that $(X \underset{\cdot}{[} \kappa{}^{\backprime}T) \mid (Y \underset{\cdot}{[} \kappa{}^{\backprime}T)$, which is the $R \mid S$ of $*350{\cdot}62$, is a member of κ. As applied to κ_ι, we have to take the representative (cf. $*332$) of the relative product; if $L \in \kappa_\iota$, we have ($*351{\cdot}42$)

$$\text{rep}_\kappa{}^{\backprime}\{(X \underset{\cdot}{[} \kappa_\iota{}^{\backprime}L) \mid (Y \underset{\cdot}{[} \kappa_\iota{}^{\backprime}L)\} = (X +_s Y) \underset{\cdot}{[} \kappa_\iota{}^{\backprime}L,$$

provided κ is open and connected and submultipliable.

The fact that the above propositions can be proved for suitable vector-families constitutes the reason for studying such families, as we did in Section B. The proof of the above propositions, together with other elementary properties of applied ratios, occupies the first two numbers of this Section.

We proceed next ($*352$) to consider all the rational multiples of a given vector in a given family, *i.e.* all the members of a given family κ which have, to a given vector T, a ratio which is a member of $C{}^{\backprime}H'$, or, alternatively, all the members of κ_ι which have to T a ratio which is a member of $C{}^{\backprime}H_g$. It will be observed that, in virtue of $*307$, if R and S have a ratio X which is a member of $C{}^{\backprime}H'$, R and $\breve{S}$ have the corresponding negative ratio $X \mid \text{Cnv}$. The members of κ which have to T a ratio which is a member of $C{}^{\backprime}H'$ are those vectors R for which we have

$$(\exists X) \,.\, X \in C{}^{\backprime}H' \,.\, RXT,$$

i.e. using the notation of $*336$, those for which we have

$$(\exists X) \,.\, X \in C{}^{\backprime}H' \,.\, RA_TX.$$

Thus they constitute the class

$$\kappa \cap A_T{}^{\backprime\backprime}C{}^{\backprime}H'.$$

Assuming that $T \in \kappa$, the vector which has the ratio X to T is $\kappa \rceil A_T{}^{\backprime}X$. This is the vector whose measure is X when T is the unit. Thus $\kappa \rceil A_T \upharpoonright C{}^{\backprime}H'$ is the correlator of a vector with its measure. It is easy to prove ($*352{\cdot}12$) that $\kappa \rceil A_T \upharpoonright C{}^{\backprime}H'$ is one-one.

We can arrange the vectors which are rational multiples of T in a series by correlation with their measures, putting vectors with smaller measures before those with larger measures. The ordering relation is T_κ, where

$$T_\kappa = \kappa \upharpoonright A_T ; H' \quad \text{Df.}$$

Similarly the members of κ_ι which are positive or negative rational multiples of T may be ordered by the relation $T_{\kappa\iota}$, where

$$T_{\kappa\iota} = \kappa_\iota \upharpoonright A_T ; H_g \quad \text{Df.}$$

We prove that change of units makes no difference to T_κ, *i.e.* if S is any member of κ which is a rational multiple of T, then $S_\kappa = T_\kappa$ (∗352·45). The corresponding proposition holds for $T_{\kappa\iota}$ if S has a positive ratio to T, but if S has a negative ratio, $S_{\kappa\iota} = \breve{T}_{\kappa\iota}$ (∗352·56·57).

If κ is a serial family, T_κ is the converse of U_κ (cf. ∗336) with its field limited to rational multiples of T (∗352·72). This proposition connects the generalized form of greater and less represented by U_κ with the form of greater and less derived from greater and less among the measures of vectors, since it shows that, in a serial family, the vectors which have greater measures come later in the series $\breve{U}_\kappa$, and those with smaller measures come earlier.

We next proceed (∗353) to consider "rational" families. These are families in which every member is a rational multiple of some one unit T, *i.e.* in which

$$(\exists T) . T \in \kappa_\partial . \kappa \subset A_T{}^{\prime\prime}C^{\prime}H'.$$

It is obvious that, given any family, the rational multiples of one of its members constitute a rational sub-family. In a rational family, rationals are sufficient for measurement, and irrationals are not required. If the family has connexity, it will be serial; in fact, if T is one of its vectors and a is a member of its field, we have (cf. ∗353·32·33)

$$U_\kappa = \kappa \upharpoonright A_T ; \breve{H}' . \dot{s}^{\prime}\kappa_\partial = A_a ; \kappa \upharpoonright A_T ; \breve{H}'.$$

Thus both U_κ and $\dot{s}^{\prime}\kappa_\partial$ are ordinally similar to $\breve{H}' \upharpoonright \breve{A}_T{}^{\prime\prime}\kappa$. If κ is submultipliable, U_κ is ordinally similar to $\breve{H}'$ (∗353·44).

We proceed next (∗354) to consider "rational nets," which are important in connection with the introduction of coordinates in geometry. A rational net is obtained from a given family, roughly speaking, by selecting those vectors which are rational multiples of a given vector, and then limiting their fields to the points which can be reached by means of them from a given point. In order to make this more precise, we proceed as follows: Let us define as the "connection" of a with respect to κ the class $A_a{}^{\prime\prime}\kappa_\iota$, *i.e.* all the points which can be reached from a by a member of κ_ι. We will now define as the "a-connected derivative of κ" the class of relations obtained by limiting

the field of every member of κ to the connection of a with respect to κ. This class of relations we denote by $\text{cx}_a\text{‘}\kappa$, putting

$$\text{cx}_a\text{‘}\kappa = \complement\, (A_a\text{‘‘}\kappa_\iota)\text{‘‘}\kappa \quad \text{Df.}$$

Instead of κ, we take, in order to obtain a rational net, all the rational multiples (in κ) of a given member T of κ, *i.e.* $C\text{‘}T_\kappa$. Then $\text{cx}_a\text{‘}C\text{‘}T_\kappa$ is a rational net, namely the rational net associated with the origin a and the unit vector T.

In proving propositions concerning the rational net $\text{cx}_a\text{‘}C\text{‘}T_\kappa$, we often require the hypothesis that κ is a group. In order to avoid having to make this hypothesis concerning our original family, we construct a closely allied family, which is always a group when κ is connected. This family, which we call κ_g, is obtained from κ by including the converses of those members of κ, if any, whose domains are equal to their converse domains, *i.e.* we put

$$\kappa_g = \kappa \cup \text{Cnv}\text{‘‘}(\kappa \cap \overleftarrow{\text{D}}\text{‘}s\text{‘}\text{Cl}\text{‘‘}\kappa) \quad \text{Df.}$$

Then if κ is a connected family, κ_g is a connected family which is a group (*354·14·16), and $(\kappa_g)_\iota = \kappa_\iota$ (*354·15). Then putting $\lambda = \kappa_g$, we take $\text{cx}_a\text{‘}C\text{‘}T_\lambda$ rather than $\text{cx}_a\text{‘}C\text{‘}T_\kappa$ as the rational net to be considered. If κ is an open and connected family, this rational net is a family which is open, connected, rational, transitive and asymmetrical (*354·41).

We proceed next (*356) to the application of real numbers to vector-families. For the application of real numbers, it is essential that our family should be serial. Given a serial family in which a given vector S is the limit (in the series U_κ) of a set of vectors which are rational multiples of another vector R, it is natural to take as the measure of S, with the unit R, the limit of the measures of the vectors whose limit is S. It is convenient to take our real numbers in the relational form given in *314, *i.e.* if ξ is a segment of H, we take $\dot{s}\text{‘}\xi$ as the corresponding real number. Thus positive real numbers are the class $\dot{s}\text{‘‘}C\text{‘}\Theta$, while positive and negative real numbers together with zero are the class $\dot{s}\text{‘‘}C\text{‘}\Theta_g$. If $\xi \in C\text{‘}\Theta$, a vector which has to R a ratio which is a member of ξ has a measure which is less than $\dot{s}\text{‘}\xi$. The class of all such vectors is $\overrightarrow{\dot{s}\text{‘}\xi}\text{‘}R$, *i.e.* if $X = \dot{s}\text{‘}\xi$, it is $\overrightarrow{X}\text{‘}R$. The limit of such vectors in the series U_κ, if it exists, will naturally be taken as the vector whose measure is X. Remembering that U_κ proceeds from greater to smaller vectors, we see that the first vector which is greater than every member of $\overrightarrow{X}\text{‘}R$ will be the *lower* limit of $\overrightarrow{X}\text{‘}R$ with respect to U_κ. Hence, if we write $X_\kappa\text{‘}R$ for the vector whose measure with the unit R is X, we have

$$X_\kappa\text{‘}R = \text{prec}\,(U_\kappa)\text{‘}\overrightarrow{X}\text{‘}R.$$

Hence we may take as our definition of X_κ

$$X_\kappa = \text{prec}\,(U_\kappa) \,|\, \overrightarrow{X} \restriction \kappa \quad \text{Df.}$$

Then X_κ is an "applied" real number.

The properties to be proved concerning applied real numbers almost all require that the family to which they are applied should be serial and submultipliable, and most of them also require that $\mathrm{Cnv}`\dot{s}`\kappa_\partial$ should be semi-Dedekindian. Assuming this, we can prove that, if $X, Y \epsilon \dot{s}``C`\Theta$, $X_\kappa \upharpoonright \kappa$ is one-one, and, with various hypotheses,

$$(X \upharpoonright \kappa) | (Y \upharpoonright \kappa) = (X \times_r Y) \upharpoonright \kappa \quad (*356{\cdot}31),$$

$$X_\kappa | Y_\kappa = (X \times_r Y)_\kappa \quad (*356{\cdot}33),$$

$$(X_\kappa`R) | (Y_\kappa`R) = (X +_r Y)_\kappa`R \quad (*356{\cdot}54).$$

These are the essential properties required of measurement, as in the analogous case of ratios.

We might proceed to consider "real" multiples of a given vector, and "real" nets. But these subjects have less importance than in the analogous case of rationals, and are therefore not discussed.

The Section ends (*359) with a number on existence-theorems for vector-families. The most important of these are derived from rationals and real numbers. The family whose members are of the form $(+_s X) \upharpoonright C`H'$, where $X \epsilon C`H'$, is initial, serial, and submultipliable (*359·21). The family whose members are of the form $(+_p \mu) \upharpoonright C`\Theta'$, where $\mu \epsilon C`\Theta'$, is initial, serial, and submultipliable, and has $\mathrm{Cnv}`\dot{s}`\kappa_\partial = \Theta'$, so that $\mathrm{Cnv}`\dot{s}`\kappa_\partial \epsilon \text{semi Ded}$ (*359·31). Finally we prove that the properties of families are unaffected by the application of correlators, whence it follows that, given any series P whose relation-number is $\dot{1} \dotplus \eta$, or is θ' where $\theta' \dotplus \dot{1} = \theta$, there is an initial serial submultipliable family κ such that $\mathrm{Cnv}`\dot{s}`\kappa_\partial = P$. Such a family may be used for the measurement of distances in P.

It is of some interest to observe that, given a suitable family κ, ratios with their field limited to κ_∂ form a family whose field is κ_∂. In this family, the zero vector is $(1/1) \upharpoonright \kappa_\partial$, and the family is connected if κ is a rational family. If we wish to obtain a serial family, we must limit ourselves to ratios not less than 1/1, *i.e.* to

$$\upharpoonright \kappa_\partial `` \overleftarrow{H_*}`(1/1).$$

This family is serial, and if we call it λ, we have (with a suitable hypothesis)

$$\dot{s}`\lambda_\partial = U_\kappa \upharpoonright \kappa_\partial.$$

It is necessary, however, if we are to obtain a family, that our original family should be submultipliable, since otherwise we do not necessarily have $\mathrm{G}`X \upharpoonright \kappa_\partial = \kappa_\partial$. For this reason, we cannot use the family of ratios without a frequent loss of generality in the resulting theorems.

The theory of measurement developed in this Section is only applicable to open families. The application of ratio to cyclic families is more complicated and is considered separately in Section D.

$*350$. RATIOS OF MEMBERS OF A FAMILY.

Summary of $*350$.

In this number we introduce no new definitions, but merely bring together the propositions of $*303$ on the pure theory of ratio, and the propositions of $*333$ on powers of vectors in open connected families, especially $*333{\cdot}47{\cdot}48$. We thus find that, if κ is an open connected family, and μ, ν are inductive cardinals which are not both zero,

$$M\{(\mu/\nu)\upharpoonright\kappa_\iota\}N \,.\equiv.\, M, N \in \kappa_\iota \,.\, \exists ! M^\nu \dot\cap N^\mu \,. \qquad (*350{\cdot}4)$$

$$\equiv.\, M, N \in \kappa_\iota \,.\, \text{rep}_\kappa{}^{\backprime}M^\nu = \text{rep}_\kappa{}^{\backprime}N^\mu \qquad (*350{\cdot}41),$$

while if R, T are members of κ,

$$R\,(\mu/\nu)\,T \,.\equiv.\, R^\nu = T^\mu \qquad (*350{\cdot}43).$$

We prove also, by means of $*333{\cdot}53$, that if L and M are members of κ_ι other than $I \upharpoonright s{}^{\backprime}\text{C}{}^{\backprime\backprime}\kappa$, they cannot have more than one ratio, *i.e.*

$*350{\cdot}44$. $\vdash : \kappa \in FM\,\text{ap}\,\text{conx} \,.\, X, Y \in C{}^{\backprime}H' \,.\, \exists ! X \upharpoonright \kappa_{\iota\partial} \dot\cap Y \upharpoonright \kappa_{\iota\partial} \,.\supset.\, X = Y$

We next prove that any ratio other than 0_q and ∞_q becomes one-one when its field is limited to κ_ι ($*350{\cdot}5$), while 0_q becomes one-many ($*350{\cdot}51$) and ∞_q becomes many-one ($*350{\cdot}511$), 0_q being in fact the ratio of the zero vector $I \upharpoonright s{}^{\backprime}\text{C}{}^{\backprime\backprime}\kappa$ to any member of κ_ι, and ∞_q being the converse of 0_q.

We consider next the multiplication and addition of ratios, but in this subject we cannot obtain some of the main theorems without the hypothesis that our family is submultipliable (introduced in $*351$). In the present number, we prove that, if κ is an open connected family, and μ, ν are inductive cardinals other than 0,

$$(\mu/1)\upharpoonright\kappa_\iota \,|\, (1/\nu)\upharpoonright\kappa_\iota \subset (\mu/\nu)\upharpoonright\kappa_\iota \qquad (*350{\cdot}53),$$

$$(1/\nu)\upharpoonright\kappa_\iota \,|\, (\mu/1)\upharpoonright\kappa_\iota = (\mu/\nu)\upharpoonright\kappa_\iota \qquad (*350{\cdot}54),$$

$$(\mu/1)\upharpoonright\kappa_\iota \,|\, (\nu/1)\upharpoonright\kappa_\iota = \{(\mu \times_c \nu)/1\}\upharpoonright\kappa_\iota \qquad (*350{\cdot}55),$$

and

$$(1/\mu)\upharpoonright\kappa_\iota \,|\, (1/\nu)\upharpoonright\kappa_\iota = \{1/(\mu \times_c \nu)\}\upharpoonright\kappa_\iota \qquad (*350{\cdot}56).$$

Hence we find that, if X, Y are ratios other than 0_q and ∞_q,

$$X\upharpoonright\kappa_\iota \quad Y\upharpoonright\kappa_\iota \subset (X \times_s Y)\upharpoonright\kappa_\iota \qquad (*350{\cdot}6),$$

while if R, S, T are members of κ,

$$RXT \,.\, SYT \,.\supset.\, (R \,|\, S)(X +_s Y)\,T \qquad (*350{\cdot}62),$$

and if L, M, N are members of κ_ι,

$$LXN \,.\, MYN \,.\supset.\, \{\text{rep}_\kappa{}^{\backprime}(L \,|\, M)\}(X +_s Y)\,N \qquad (*350{\cdot}63).$$

We then prove similar results for subtraction, and thus arrive at the following proposition concerning generalized addition of positive or negative ratios:

$*351$. SUBMULTIPLIABLE FAMILIES.

Summary of $*351$.

A "submultipliable" family is one in which any vector can be divided into ν equal parts (where ν is any inductive cardinal other than 0), *i.e.* in which, if $R \epsilon \kappa$, there is a vector S which is a member of κ and is such that $S^\nu = R$. The definition is

$*351 \cdot 01$. FM subm $=$

$$FM \cap \hat{\kappa} \{R \epsilon \kappa \,.\, \nu \epsilon \mathrm{NC\,ind} - \iota`0 \,.\, \supset_{R,\nu} \,.\, (\exists S) \,.\, S \epsilon \kappa \,.\, R = S^\nu\} \quad \mathrm{Df}$$

In open families, such as we are considering in this Section, S will be unique when R and ν are given. But in cyclic families, as we shall show in Section D, there will be ν values of S. For example, let κ be a family of angles. Then the vector-angle $2\mu\pi/\nu$ has its νth power equal to 2π for any integral value of μ, since $2\mu\pi$ is the same vector as 2π; and $2\mu\pi/\nu$ has ν different values, since, considered as a vector, any angle θ is identical with $\theta + 2\pi$. In the present Section, however, these complications are excluded, owing to the fact that we confine our attention to open families.

In virtue of $*337 \cdot 27$, a family is submultipliable if it is serial and $\mathrm{Cnv}`\dot{s}`\kappa_\partial$ is compact and semi-Dedekindian ($*351 \cdot 11$).

When κ is a family which is open, connected, and submultipliable, if $L \epsilon \kappa_\iota$ and $\mu \epsilon \mathrm{NC\,ind} - \iota`0$, we have

$$(\exists M) \,.\, M \epsilon \kappa_\iota \,.\, \mathrm{rep}_\kappa`M^\mu = L \quad (*351 \cdot 2).$$

Hence if X is any ratio (excluding ∞_q, now and always henceforth), we have

$$\mathrm{E}\,!\, X \upharpoonright \kappa_\iota`L \quad (*351 \cdot 21).$$

In order to obtain the same result for κ, we have to assume that all powers of members of κ are members of κ ($*351 \cdot 22$), but we can obtain the same result for $\kappa \cup \mathrm{Cnv}``\kappa$ without this assumption ($*351 \cdot 221$), because of $*331 \cdot 54$, which shows that in any connected family all powers of members of $\kappa \cup \mathrm{Cnv}``\kappa$ are members of $\kappa \cup \mathrm{Cnv}``\kappa$.

In virtue of the above propositions, the propositions on products and sums of ratios, which in $*350$ only stated inclusions, now state identities. Thus if $X, Y \epsilon C`H'$, we have

$$(X \upharpoonright \kappa_\iota) \,|\, (Y \upharpoonright \kappa_\iota) = (X \times_s Y) \upharpoonright \kappa_\iota \quad (*351 \cdot 31),$$

$$\mathrm{rep}_\kappa`\{(X \upharpoonright \kappa_\iota`L) \,|\, (Y \upharpoonright \kappa_\iota`L)\} = (X +_s Y) \upharpoonright \kappa_\iota`L \quad (*351 \cdot 42),$$

where $L \epsilon \kappa_\iota$; also

$$\text{rep}_\kappa\text{‘}\{(X \upharpoonleft \kappa_\iota\text{‘}L) \mid (Y \upharpoonleft \kappa_\iota\text{‘}\breve{L})\} = (X -_s Y) \upharpoonleft \kappa_\iota\text{‘}L \quad (*351\cdot45).$$

The corresponding propositions for ratios confined to κ instead of to κ_ι require the additional hypothesis $s\text{‘Pot“}\kappa \subset \kappa$, because this hypothesis is required in $*351\cdot22$; on the other hand, in the analogue of $*351\cdot42$ "rep_κ" does not appear, and we have (with the above hypothesis)

$$(X \upharpoonleft \kappa\text{‘}R) \mid (Y \upharpoonleft \kappa\text{‘}R) = (X +_s Y) \upharpoonleft \kappa\text{‘}R \quad (*351\cdot43),$$

where $R \epsilon \kappa$. For ratios confined to $\kappa \cup \text{Cnv“}\kappa$ instead of to κ, the corresponding result can be proved without the hypothesis $s\text{‘Pot“}\kappa \subset \kappa$ ($*351\cdot431$). It will be observed that the hypothesis $s\text{‘Pot“}\kappa \subset \kappa$ is satisfied if κ is a group, though it may also be satisfied when κ is not a group. Since a transitive connected family is a group, a transitive connected family always satisfies $s\text{‘Pot“}\kappa \subset \kappa$, as has been proved already ($*334\cdot132$).

*352. RATIONAL MULTIPLES OF A GIVEN VECTOR.

Summary of *352.

By a "rational multiple" of a given vector in a family κ we mean, if we are dealing with κ, any vector in the family which has to the given vector a relation which is a member of $C'H'$, and if we are dealing with κ_ι, we mean any member of κ_ι which has to the given member of κ_ι a relation which is a member of $C'H_g$. We will call the former "rational κ-multiples" and the latter "*generalized* rational multiples." It will be observed that if κ contains pairs of members which are each other's converses, only one member of such a pair can be contained among the rational κ-multiples of a given member of κ, provided κ is an open family. Hence the rational κ-multiples of a given vector all have one "sense," even if this was not the case with the original family.

Rational multiples of a given vector T can be arranged in a series by correlation with their measures with T as unit. These measures are ordered, in the case of rational κ-multiples, by the relation H', and in the case of generalized rational multiples, by the relation H_g. Moreover if X is the measure of a given member of κ with T as unit, the given member of κ is $\kappa \rceil A_T{}^{\backprime}X$; while if X is the measure of a given member of κ_ι, the given member of κ_ι is $\kappa_\iota \rceil A_T{}^{\backprime}X$. Hence the rational κ-multiples of T are ordered by the relation $\kappa \rceil A_T ; H'$, and the generalized rational multiples are ordered by the relation $\kappa_\iota \rceil A_T ; H_g$. These two relations, therefore, are the relations we shall consider in this number. We put

***352·01.** $T_\kappa = \kappa \rceil A_T ; H'$ Df

***352·02.** $T_{\kappa\iota} = \kappa_\iota \rceil A_T ; H_g$ Df

We assume throughout this number that κ is open and connected. In dealing with T_κ, we assume $T \in \kappa_\partial$, and in dealing with $T_{\kappa\iota}$, we assume $T \in \kappa_{\iota\partial}$. We then prove the following propositions among others:

$$\kappa \rceil A_T \upharpoonright C'H' \in 1 \to 1 \quad (*352{\cdot}12),$$

$$\kappa_\iota \rceil A_T \upharpoonright C'H_g \in 1 \to 1 \quad (*352{\cdot}15),$$

i.e. the relation of a rational multiple of T to its measure is one-one.

$$T_\kappa, T_{\kappa\iota} \epsilon \mathrm{Ser} \quad (*352\cdot16\cdot17).$$

Observe that this requires only that κ should be open and connected. The serial property results from the correlation with H' or H_g.

$$C`T_\kappa = \kappa \cap A_T``C`H' \,.\, C`T_{\kappa\iota} = \kappa_\iota \cap A_T``C`H_g \quad (*352\cdot3\cdot31).$$

If S is any non-zero member of $C`T_\kappa$, $C`S_\kappa = C`T_\kappa$ ($*352\cdot41$), *i.e.* the rational $\kappa$-multiples of $T$ are the same as those of any rational $\kappa$-multiple of $T$; with a similar proposition for $C`T_{\kappa\iota}$ ($*352\cdot42$).

$$RT_\kappa S \,.\equiv: R, S \epsilon \kappa \cap A_T``C`H' : (\exists \mu, \nu) \,.\, \mu, \nu \epsilon \mathrm{NC\,ind} \,.\, \mu < \nu \,.\, R^\nu = S^\mu \quad (*352\cdot43).$$

This is a convenient formula for T_κ, and leads immediately to

$$T_\kappa = \{\dot{s}`\overrightarrow{H'}`(1/1)\} \upharpoonright (\kappa \cap A_T``C`H') \quad (*352\cdot44).$$

Observe that $\overrightarrow{H'}`(1/1)$ is the class of rational proper fractions, including $0_q$. By $*352\cdot44$ and $*352\cdot41\cdot3$, we see that, if $S \neq I \upharpoonright s`\mathrm{C}``\kappa$,

$$S \epsilon C`T_\kappa \,.\supset.\, S_\kappa = T_\kappa \quad (*352\cdot45),$$

i.e. the order of magnitude of a set of vectors which are rational κ-multiples of a given unit is independent of the choice of the unit.

In order to establish the analogous property for $T_{\kappa\iota}$, we first prove a formula analogous to $*352\cdot44$, namely

$$T_{\kappa\iota} = \mathrm{Cnv}\,;\{\dot{s}`\overleftarrow{H}`(1/1)\} \upharpoonright (\kappa_\iota \cap A_T``C`H) \,\dot{+}\, \{\dot{s}`\overrightarrow{H'}`(1/1)\} \upharpoonright (\kappa_\iota \cap A_T``C`H') \quad (*352\cdot54).$$

Here the first term gives the series of negative multiples of T, while the second gives the series of positive multiples of T (including $I \upharpoonright s`\mathrm{C}``\kappa$).

From the above formula it follows, as in the case of T_κ, that if S is a positive multiple of T (not including $I \upharpoonright s`\mathrm{C}``\kappa$), $S_{\kappa\iota} = T_{\kappa\iota}$, while if S is a negative multiple of T, $S_{\kappa\iota} = \breve{T}_{\kappa\iota}$ ($*352\cdot56\cdot57$).

Finally we deal with the relation of U_κ to T_κ. Here we have to assume that κ is a *serial* family. We then find that U_κ with its field confined to rational κ-multiples of T is the converse of T_κ, *i.e.* we have

$*353$. RATIONAL FAMILIES.

Summary of $*353$.

A "rational family" is one which consists entirely of positive rational multiples of one of its members. We denote rational families by "$FM\,\mathrm{rt}$"; the definition is

$*353{\cdot}01$. $FM\,\mathrm{rt} = FM \cap \hat{\kappa}\{(\exists T) . T \epsilon \kappa_\partial . \kappa \subset A_T``C`H'\}$ Df

It is obvious that, if κ is any family, $\kappa \cap A_T``C`H'$, which we considered in the last number, is a rational family. If $\kappa$ is a connected family, it does not follow that $\kappa \cap A_T``C`H'$ is a connected family, but the proofs of its properties, as we saw in $*352$, make use of the fact that it is contained in a connected family. Many of the most important properties of connected families hold equally of sub-classes of connected families, notably the property that two members of κ or κ_ι whose logical product exists are identical ($*331{\cdot}42{\cdot}24$). In dealing with rational families, a good many propositions can be proved by merely assuming that they are contained in connected families. We put

$*353{\cdot}02$. $FM\,\mathrm{cx} = FM \cap \hat{\lambda}\{(\exists\kappa) . \kappa \epsilon FM\,\mathrm{conx} . \lambda \subset \kappa\}$ Df

$*353{\cdot}03$. $FM\,\mathrm{rt}\,\mathrm{cx} = FM\,\mathrm{rt} \cap FM\,\mathrm{cx}$ Df

We will call a family "sub-connected" when it is contained in a connected family. When a family κ is open, rational, and sub-connected, any member of κ_∂ may be taken as the T of the definition $*353{\cdot}01$ (this is proved in $*353{\cdot}13$); and if S, T are any two members of κ_∂, some power of S will be identical with some power of T ($*353{\cdot}12$). An open rational sub-connected family is asymmetrical ($*353{\cdot}2$); no power of a member, and no product of two members, is the converse of a non-zero member ($*353{\cdot}22{\cdot}23$). Hence by $*331{\cdot}54{\cdot}33$, if the family is connected, and not merely sub-connected, it is a group and transitive ($*353{\cdot}25{\cdot}27$).

If λ is a family which, besides being open and rational, has connexity, then if a is a member of the field and $T \epsilon \kappa_\partial$ we shall have

$$\dot{s}`\lambda_\partial = A_a ; \lambda \upharpoonright A_T ; \breve{H}' . U_\lambda = \lambda \upharpoonright A_T ; \breve{H}' \quad (*353{\cdot}32{\cdot}33).$$

That is, the series of points in the field and the series of vectors are both

ordinally similar to part or the whole of the series of ratios; they will be similar to the whole if λ is submultipliable (*353·44). But when λ is submultipliable, a smaller hypothesis suffices, for in that case we can prove that if λ is connected, then $\lambda_\iota = \lambda \cup \mathrm{Cnv}``\lambda$ (*353·41), so that λ has connexity, and is serial (*353·42). Thus we have

*354. RATIONAL NETS.

Summary of *354.

The subject of "rational nets," which is to be considered in this number, is of importance for the introduction of coordinates in geometry. We have three stages in the construction of a rational net. First, taking any vector T in a family κ, we construct $C'T_\kappa$, *i.e.* the positive rational multiples of T, as in *352. The result is, as a rule, a family which is not connected, even when the family κ is connected. For if there are in κ any vectors other than $C'T_\kappa$, any point of the field which is reached from a given point a by one of these "irrational" vectors cannot be reached from a by a member of $C'T_\kappa$, though it will be in the field of $C'T_\kappa$. Thus in order to obtain from $C'T_\kappa$ a connected family, we shall have to limit the fields of its members to the points which can be reached from a given point a by one or more rational steps backwards or forwards, *i.e.* to the points $A_a``(C'T_\kappa)_\iota$. It will be observed that whereas, in the construction of $C'T_\kappa$, only positive vectors are used, negative vectors, *i.e.* the converses of positive vectors, are also admitted in constructing what we may call the "rational points" with respect to a and T. Having constructed these points, *i.e.* the class $A_a``(C'T_\kappa)_\iota$ we then proceed to the third and last stage in constructing a rational net, by limiting the field of every member of $C'T_\kappa$ to $A_a``(C'T_\kappa)_\iota$.

Many of the propositions concerning rational nets require the hypothesis that the family concerned is a group. If this is not the case with the family κ from which we start, we replace κ by κ_g, where κ_g is formed by adding to κ the converses of those members of κ (if any) whose domains are identical with the common converse domain of members of κ. The definition is

***354·01.** $\kappa_g = \kappa \cup \mathrm{Cnv}``(\kappa \cap \overleftarrow{\mathrm{D}}`s`\mathrm{G}``\kappa)$ Df

We put also

***354·03.** $FM\,\mathrm{grp} = FM \cap \hat{\kappa}(s`\kappa \,|\, ``\kappa \subset \kappa)$ Df

We then easily prove that if κ is connected, κ_g is a group (*354·14), and if κ is open and connected, κ_g is open and connected and a group (*354·17). If κ is connected, $(\kappa_g)_\iota = \kappa_\iota$ (*354·15), so that properties only dependent on κ_ι, like that of openness, always hold for κ_g when they hold for κ.

Next, we prove that if κ is open, connected, and a group, $C'T_\kappa$ is open, rational, sub-connected and a group (*354·22). Hence if κ is open and connected, and $\lambda = \kappa_g$, $C'T_\lambda$ is open, rational, sub-connected and a group (*354·24).

The "rational points" with respect to a and T are $A_a``(C'T_\kappa)_\iota$. In order to study them, we consider $A_a``\lambda_\iota$, where λ is a family concerning which we make hypotheses which will be fulfilled in the case of $C'T_\kappa$. We prove that if λ is a family which is a group, and $S \in \lambda \,.\, a \in s`\text{Cl}``\lambda$, then

$$A_a``\lambda_\iota \subset \breve{S}``A_a``\lambda_\iota \quad (*354·31),$$

whence $\quad S \upharpoonright (A_a``\lambda_\iota) = (A_a``\lambda_\iota) \upharpoonright S = S \upharpoonright (A_a``\lambda_\iota) \quad (*354·312).$

Next we prove that, with the same hypothesis, if b is any other member of $A_a``\lambda_\iota$, then

$$A_a``\lambda_\iota = A_b``\lambda_\iota \quad (*354·33).$$

Thus the rational points with respect to a and T are the same as the rational points with respect to b and T, if b is one of these rational points.

The "rational net" is the family $\upharpoonright \{A_a``(C'T_\kappa)_\iota\}``C'T_\kappa$. Writing λ for $C'T_\kappa$, this becomes $\upharpoonright (A_a``\lambda_\iota)``\lambda$. In order to obtain the properties of the rational net, we therefore continue to consider a family λ, concerning which we make hypotheses which are verified in the case of $C'T_\kappa$, and we put

***354·02.** $\text{cx}_a`\lambda = \upharpoonright (A_a``\lambda_\iota)``\lambda \quad \text{Df}$

Thus $\text{cx}_a`C'T_\kappa$ is the rational net defined by $\kappa$, $T$, and $a$. We prove (*354·4) that if $\lambda$ is a group, $\text{cx}_a`\lambda$ is a family whose field is $A_a``\lambda_\iota$. We prove that if $\lambda$ is a family, and $a$ a member of its field such that any member $L$ of $\lambda_\iota$ for which $L`a$ exists is a member of $\lambda \cup \text{Cnv}``\lambda$, then a is a connected point of $\text{cx}_a`\lambda$, *i.e.*

***354·32** $\vdash : \lambda \in FM \,.\, a \in s`\text{Cl}``\lambda \,.\, \lambda_\iota \cap \text{Cl}`A_a \subset \lambda \cup \text{Cnv}``\lambda \,.\, \supset .\, a \in \text{conx}`\text{cx}_a`\lambda$

The hypothesis $\lambda_\iota \cap \text{Cl}`A_a \subset \lambda \cup \text{Cnv}``\lambda$ would be verified if λ were a connected family and a were a connected point of λ. But we want to be able to replace λ by $C'T_\kappa$, which is in general not connected. The above hypothesis, unlike $\lambda \in FM\,\text{conx}$, is satisfied by $C'T_\kappa$, provided κ is open and a group and a is a connected point of κ (*354·34). Hence it follows that if κ is a family which is open, connected, and a group, and a is a connected point of κ, $\text{cx}_a`C'T_\kappa$ is open and connected, and $a$ is a connected point of $\text{cx}_a`C'T_\kappa$ (*354·401). Again, in virtue of *354·312, if λ is a family which is a group, and a is any member of its field, $\text{cx}_a`\lambda$ is a group (*354·313); hence when $\kappa$ is a family which is open, connected, and a group, $\text{cx}_a`C'T_\kappa$ is a group (*354·402); and it is easy to prove that it is also a rational family (*354·403). Hence, by *353·27, $\text{cx}_a`C'T_\kappa$ is a family which is open, connected, rational, a group, transitive, and asymmetrical (*354·404). If our original family is open and connected but not a group, we only have to

substitute κ_g for κ, *i.e.* putting $\lambda = \kappa_g$, we only have to take $\text{cx}_a{}'C'T_\lambda$, in order to obtain a rational net with all the above properties. This is stated in the proposition

*356. MEASUREMENT BY REAL NUMBERS.

Summary of *356.

In this number we consider the application of real numbers to the measurement of vectors in a family. The principle of this application is as follows: If a given set of vectors, all of which are rational multiples of a given vector R, have a limit with respect to U_κ, and if their measures determine a segment of H, then we take the real number represented by this segment as the measure of the limit of the given set of vectors. For the sake of homogeneity with rational measures, it is well to take our real numbers in the relational form given in *314; *i.e.* if $\xi \in C`\Theta$, we take $\dot{s}`\xi$ as the corresponding real number. With a suitable hypothesis, the result of the above principle for applying real numbers is, where rational multiples of the unit R are concerned, to replace the ratio X by the rational real number $\dot{s}`\overrightarrow{H}`X$, as the measure of the vector $X \upharpoonright \kappa`R$ (cf. *356·63). Then the measure of the limit of a set of rational vectors will be, by our principle, the limit of their measures. Thus our principle is conformable to what is required for an application of real numbers.

It should be observed that, if any application of irrationals is to be possible, it is necessary that the vectors of the family concerned should have a serial or quasi-serial order, independently of the order generated by their measures. The order generated, among rational multiples of T, by the ratios which are measures of these multiples, is T_κ (cf. *352). A vector which is not a member of $C`T_\kappa$ cannot be the limit of any set of vectors with respect to T_κ. But we saw (*352·72) that if κ is a serial family,

$$T_\kappa = \breve{U}_\kappa \upharpoonright C`T_\kappa.$$

Hence when κ is a serial family, a vector which is not a member of $C`T_\kappa$ may be the limit of a set of members of $C`T_\kappa$ with respect to U_κ. It is the existence of an independent series U_κ, not generated by measurement, which makes the application of irrationals as measures possible.

The following phraseology may be found convenient. Taking a unit T in a family κ, and an origin a in its field, if $X \in C`H'$ and $S = X \upharpoonright \kappa`T$ and $x = S`a = (X \upharpoonright \kappa`T)`a$, we call X the "rational measure" of S and the "rational coordinate" of x. We have, in the same circumstances,

$$S = \kappa \urcorner A_T`X \,.\, x = A_a`S = A_a`\kappa \urcorner A_T`X.$$

We will call S the vector of X, and x the point of X; and the same phraseology will be employed for the vectors and points obtained by measures which are real numbers. We may now state the principle according to which we apply real numbers as measures as follows. Given a segment ξ of H, take all the vectors of ξ's: these form the class $\kappa \cap A_T``\xi$. Then the real number $\dot{s}`\xi$ is to be the measure of the limit (with respect to $U_\kappa$) of the class $\kappa \cap A_T``\xi$. Since U_κ has the opposite sense to that of T_κ, *i.e.* U_κ proceeds from the vectors with bigger measures to those with smaller ones, the limit we shall have to take will be the *lower* lim. with respect to U_κ. Thus the vector whose measure is $\dot{s}`\xi$ will be

$$\text{prec}\,(U_\kappa)`(\kappa \cap A_T``\xi).$$

Now if we put $X = \dot{s}`\xi$, $A_T``\xi = \overrightarrow{X}`T$, and $X$ is a relational real number. Hence using *206·131, the vector whose measure is $X$ is $\text{prec}\,(U_\kappa)`\overrightarrow{X}`T$. Hence if "$X_\kappa`T$" represents the vector whose measure is X (unit T), we put

***356·01.** $X_\kappa = \text{prec}\,(U_\kappa) \,|\, \overrightarrow{X} \upharpoonright \kappa$ Df

Assuming now that κ is a serial submultipliable family, in which we take R as the unit and a as the origin, and putting, for notational convenience,

$$\breve{P} = U_\kappa \,.\, \breve{Q} = \dot{s}`\kappa_\partial,$$

we have first a set of preliminary propositions (*356·1—·191), of which the most important are

$$H' = (C`H') \rceil \breve{A}_R \,;\, P = (C`H') \rceil \breve{A}_R \,;\, \breve{A}_a \,;\, Q \quad (*356·13),$$

$$P \upharpoonright C`R_\kappa = \kappa \rceil A_R \,;\, H' \quad (*356·14),$$

giving the relations between the series of ratios, the series of their vectors, and the series of their points.

We proceed next (*356·2—·26) to the proof that $X_\kappa \upharpoonright \kappa \in 1 \to 1$. This requires, in addition to our previous hypothesis, that Q should be semi-Dedekindian. With this hypothesis, we first prove that if X, Y are relational real numbers,

$$\text{Ɑ}`X_\kappa = \text{Ɑ}`Y_\kappa = \kappa_\partial : X_\kappa = Y_\kappa \,.\equiv.\, X = Y \quad (*356·21).$$

We then prove, by the help of some arithmetical lemmas, that the lower limit of the submultiples of a given vector is the zero vector, *i.e.*

$$\text{tl}_P`\hat{S}\{S \in \kappa : (\exists \nu) \,.\, R = S^\nu\} = I \upharpoonright C`Q \quad (*356·22).$$

Hence we easily prove that, if R is any non-zero vector, and λ is a class of vectors having a lower limit L, the lower limit of the relative products of R and members of λ is the relative product of R and L, *i.e.*

$$\lambda \subset \kappa \,.\, L = \text{tl}_P`\lambda \,.\, R \in \kappa_\partial \,.\supset.\, R \,|\, L = \text{tl}_P`R \,|``\lambda \quad (*356·221).$$

Remembering that the relative product is represented arithmetically by the sum, we may express the above proposition by saying that the limit of the sums of a given vector and a set of vectors is the sum of the given vector and the limit of the set. From this proposition we easily deduce that if RPS, $X_\kappa{}^{\backprime}R \nmid X_\kappa{}^{\backprime}S$, whence it follows that

$$X_\kappa \upharpoonright \kappa \epsilon 1 \rightarrow 1 \quad (*356\cdot26).$$

Our next set of propositions ($*356\cdot3$—$\cdot33$) is concerned in connecting the relative product of X_κ and Y_κ with the arithmetical product $X \times_r Y$, where "$\times_r$" has the meaning defined in $*314$. Here we only require that κ should be serial and submultipliable, and we obtain

$$X_\kappa \mid Y_\kappa = (X \times_r Y)_\kappa \quad (*356\cdot33).$$

This proposition is the analogue of $*351\cdot31$ (except that κ_ι is replaced by κ); it has a similar importance, and calls for similar remarks.

Our next set of propositions ($*356\cdot4$—$\cdot43$) is concerned in proving that the limit of the points of a segment of ratios is the point of their limit, in other words, that the limit of a set of points whose coordinates are a segment of rationals is the point whose coordinate is the limit of the segment. Here we again require that our family should be semi-Dedekindian; then if ξ is a segment of ratios, and $X = \dot{s}{}^{\backprime}\xi$, the above proposition is

$$(X_\kappa{}^{\backprime}R){}^{\backprime}a = \text{seq}_Q{}^{\backprime}A_a{}^{\backprime\backprime}A_R{}^{\backprime\backprime}\xi = \text{seq}_Q{}^{\backprime}A_a{}^{\backprime\backprime}\overrightarrow{X}{}^{\backprime}R \quad (*356\cdot43).$$

Here $X_\kappa{}^{\backprime}R$ is the vector of X, $(X_\kappa{}^{\backprime}R){}^{\backprime}a$ is the point of X; $A_R{}^{\backprime\backprime}\xi = \overrightarrow{X}{}^{\backprime}R$, and each is the class of vectors of members of ξ; and $A_a{}^{\backprime\backprime}A_R{}^{\backprime\backprime}\xi$ or $A_a{}^{\backprime\backprime}\overrightarrow{X}{}^{\backprime}R$ is the class of points of members of ξ. Moreover X is a relational real number. Thus the above proposition states that the point of X is the segment (*i.e.* the limit) of the points of the ratios contained in X; *i.e.* of the ratios which may be considered less than X.

We next proceed ($*356\cdot5$—$\cdot54$) to connect the relative multiplication of vectors with the addition of their measures. Here we require that κ should be semi-Dedekindian as well as serial and submultipliable. We then find that if X, Y are relational real numbers, and R is a non-zero vector,

$$(X_\kappa{}^{\backprime}R) \mid (Y_\kappa{}^{\backprime}R) = (X +_r Y)_\kappa{}^{\backprime}R \quad (*356\cdot54).$$

This proposition is the analogue of $*351\cdot43$, and calls for similar remarks. The proof proceeds without much difficulty by means of $*356\cdot43$.

Finally we have a set of propositions ($*356\cdot6$—$\cdot63$) to prove that the real number which measures a rational vector is the real number corresponding to the ratio which is its measure; *i.e.* if X is a ratio, the vector which has the ratio X to the unit has the real number $\dot{s}{}^{\backprime}\overrightarrow{H}{}^{\backprime}X$ for its measure. It is to be remembered that rational real numbers must not be identified with ratios,

any more than integral ratios (*i.e.* ratios of the form $\nu/1$) must be identified with cardinals. The real number corresponding to a ratio X is $\dot{s}`\overrightarrow{H}`X$; this is what we call a "rational real number." In measurement, when we are measuring by ratios, if R is our unit, X will be the measure of $X \upharpoonright \kappa`R$; but when we are measuring by real numbers, the measure of $X \upharpoonright \kappa`R$ must be a real number. The real number which is the measure of $X \upharpoonright \kappa`R$ will, by our definition, be a real number Z such that

$$X \upharpoonright \kappa`R = \text{prec}(U_\kappa)`\overrightarrow{Z}`R.$$

Thus we have to prove that, if X is a ratio, the above equation is satisfied if we put $Z = \dot{s}`\overrightarrow{H}`X$. This requires that κ should be serial, submultipliable and semi-Dedekindian; we then have

$$X \in C`H . \supset . (\dot{s}`\overrightarrow{H}`X)_\kappa = X \upharpoonright \kappa \quad (*356\cdot63).$$

Thus although the "pure" real number $\dot{s}`\overrightarrow{H}`X$ is not identical with the "pure" ratio X, yet the "applied" real number $(\dot{s}`\overrightarrow{H}`X)_\kappa$ *is* identical with the "applied" ratio $X \upharpoonright \kappa$. This fact explains why the results of the habitual confusion between a ratio and a rational real number have not been even more disastrous.

*359. EXISTENCE-THEOREMS FOR VECTOR-FAMILIES.

Summary of *359.

In this number we prove that, assuming the axiom of infinity, there are vector-families of the various kinds considered in previous numbers.

If P is any well-ordered series having no last term, the converses of the interval-relations, *i.e.* the class finid‘$\breve{P}$, form an open family of $C\text{‘}P$ (*359·11). If P is a progression, this family is serial and initial (*359·12).

The family consisting of additions of positive ratios to positive ratios (including 0_q), *i.e.* consisting of all terms of the form $(+_s X) \upharpoonright C\text{‘}H'$, where $X \epsilon C\text{‘}H'$, is initial, serial, open, and submultipliable (*359·21), assuming the axiom of infinity. The family consisting of generalized additions of positive ratios to generalized ratios is serial, open, and submultipliable, but not initial (*359·25).

The family consisting of multiplications of positive ratios not 0_q by positive ratios not 0_q is open and connected, but not serial or submultipliable (*359·22); if we confine the multipliers to ratios not less than 1/1, the family becomes serial (*359·25).

The family consisting of additions of positive real numbers to positive real numbers (including $\iota\text{‘}0_q$) is serial, initial, and submultipliable (*359·31); the family consisting of generalized additions of positive real numbers (including $\iota\text{‘}0_q$) to generalized real numbers is serial and submultipliable, but not initial (*359·32). Similar propositions hold for multiplication, provided $\iota\text{‘}0_q$ is omitted; but the resulting families will not be serial. In the case where the field is confined to positive real numbers, however, the family becomes serial if the multipliers are confined to such as are not less than $\overrightarrow{H}\text{‘}(1/1)$, which is the real number 1.

The last set of propositions in this number (*359·4—·44) are concerned in proving that, given a family κ whose field is β, if S is a correlator of α and β, $S\dagger\text{“}\kappa$ is a family whose field is α, and which has the same properties of being connected, open, etc. as the original family κ. Hence if κ is a family whose field is the real numbers, and we are given any class α similar to the real numbers (in other words the field of any continuous series), if S is the correlator

of this class with the real numbers, $S\dagger``\kappa$ gives a family whose field is α. Hence from our previous existence-theorems we derive the existence, for α, of an initial serial family, giving us a system of measurement for α. Similarly if α is similar to the rationals.

SECTION D.

CYCLIC FAMILIES.

Summary of Section D.

The theory of measurement hitherto developed has been only applicable to *open* families. But in order to be able to deal with such cases as the angles at a point, or the elliptic straight line, we require a theory of measurement applicable to families which are not open. This theory is given briefly in the present Section.

When a family is not open, two vectors which have one ratio will usually also have many others, *i.e.* we shall not have $\dot{\exists} ! X \upharpoonright \kappa \dot{\frown} Y \upharpoonright \kappa . \supset . X = Y$, where X, Y are ratios. Also a ratio confined to the family will not usually be one-one. Under these circumstances, it is necessary, if measurement is to be possible, that there should be some way of distinguishing one among the ratios of two vectors as their "principal" ratio, and of then showing that, by confining ourselves to principal ratios, the requisite properties of ratios reappear.

The case of angles will serve to illustrate our procedure. Considered geometrically, not kinematically, a vector which is a multiple of 2π is identical with the null-vector, and if θ is any angle, $\theta = 2\nu\pi + \theta$, where ν is any integer positive or negative. We are here considering an angle as a vector whose field is all the rays in a given plane through a given point. Thus there will be two angles which are half of the null-vector, namely π and 2π, and four angles which are a quarter of the null-vector, namely $\pi/2$, π, $3\pi/2$ and 2π; and so on. The ratio of $\pi/2$ to π is any number of the form $(2\mu + 1)/(4\nu + 2)$; thus two terms may have many different ratios.

In order to evade this difficulty, we first arrange angles in a series ending with 2π, and having no first term, but proceeding from smaller to greater angles. Then the angles which have a given ratio μ/ν to a given angle will be finite in number, and therefore one of them will be the smallest. We take this as the "principal" angle having the ratio μ/ν to the given angle, and define "$(\mu/\nu)_\kappa$" to mean the relation between two angles consisting in the fact that the first is the "principal" angle having the ratio μ/ν to the second. Then of all the ratios between the two angles, the ratio μ/ν may be regarded

as the "principal" ratio. It will be found that, with suitable hypotheses, $(\mu/\nu)_\kappa$ has the properties required in order to make measurement possible.

In order to make the above method feasible, certain properties must be assumed to hold concerning the family κ. (These properties are all verified in the cases that arise in practice.) We shall therefore only speak of a family as cyclic when it fulfils the following conditions:

(1) It must be connected.

(2) It must contain a non-zero member which is identical with its converse. This is the property which makes the family cyclic. In the case of angles, the member in question is π.

(3) It must be such that $\kappa_\partial \upharpoonright U_\kappa$ is transitive. This is the property which enables us to arrange the field in a series. It will be observed that U_κ cannot be transitive, since, if K_κ is the member which is its own converse, we have

$$(I \upharpoonright s'\mathrm{C}''\kappa)\, U_\kappa K_\kappa \,.\, K_\kappa U_\kappa (I \upharpoonright s'\mathrm{C}''\kappa),$$

but we do not have $(I \upharpoonright s'\mathrm{C}''\kappa)\, U_\kappa (I \upharpoonright s'\mathrm{C}''\kappa)$, because U_κ is contained in diversity (by $*336{\cdot}6$). It is, however, possible that U_κ should be transitive so long as we do not start from $I \upharpoonright s'\mathrm{C}''\kappa$, and this we assume as part of the definition of cyclic families.

(4) In order to avoid trivial exceptions, we assume that κ does not have only two members, since otherwise it might consist only of $I \upharpoonright s'\mathrm{C}''\kappa$ and K_κ.

We are thus led to the following definition:

$$FM\,\mathrm{cycl} = (FM\,\mathrm{conx} - 2) \cap \hat{\kappa}\,\{\kappa_\partial \upharpoonright U_\kappa \,\epsilon\, \mathrm{trans} : (\exists K) \,.\, K \,\epsilon\, \kappa_\partial \,.\, K = \breve{K}\} \quad \mathrm{Df.}$$

We prove that there is only one such relation as K, and therefore put

$$K_\kappa = (\imath K)(K \,\epsilon\, \kappa_\partial \,.\, K = \breve{K}) \quad \mathrm{Df.}$$

Also for the sake of brevity we put

$$I_\kappa = I \upharpoonright s'\mathrm{C}''\kappa \qquad \mathrm{Df.}$$

We then prove that κ is a family having connexity, and satisfying the condition

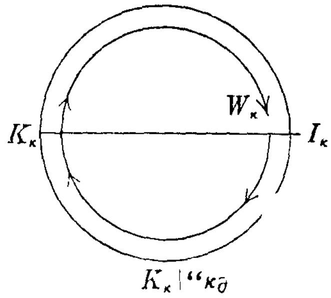
$$\mathrm{D}''\kappa = \mathrm{C}''\kappa,$$

i.e. having the domain of a member always identical with the common converse domain. Thus by $*334{\cdot}21$, $\kappa_\iota = \kappa \cup \mathrm{Cnv}''\kappa$.

In a cyclic family, $\kappa \cup \mathrm{Cnv}''\kappa$ consists of two mutually exclusive parts, namely κ_∂ and $K_\kappa |''\kappa_\partial$. (In the case of angles, $K_\kappa | R$ would be $\pi + R$. Thus κ_∂ would be the angles from 0 (exclusive) to π (inclusive), and $K_\kappa |''\kappa_\partial$ would be the angles from π (exclusive) to 2π (inclusive).) Also $K_\kappa |''\kappa_\partial$ consists of the converses of $\kappa - \iota' K_\kappa$.

We take up next ($*371$) the question of arranging $\kappa \cup \mathrm{Cnv}''\kappa$ in a series. For this purpose, in order to avoid circularity, we have to erect a barrier at some point; we choose I_κ as this point. By the definition of cyclic families,

$\kappa_\partial \upharpoonleft U_\kappa$ is transitive; hence, since the family has connexity, $U_\kappa \upharpoonright \kappa_\partial$ is serial. This relation therefore arranges all the members of κ_∂ in a series, beginning with K_κ and proceeding towards I_κ. In order to extend our series to $K_\kappa | ``\kappa_\partial$, we only have to make $K_\kappa | R$ precede $K_\kappa | S$ if $R$ precedes $S$, where $R$ and $S$ are members of $\kappa_\partial$. That is, we arrange $K_\kappa | ``\kappa_\partial$ in the order $K_\kappa |; U_\kappa \upharpoonright \kappa_\partial$. This gives a series which begins with I_κ and proceeds towards K_κ without reaching it. Thus taking the sum of the above two series (in the sense of $*160$), we get a series whose field is $\kappa \cup \mathrm{Cnv}``\kappa$, which begins with $I_\kappa$, travels through $K_\kappa | ``\kappa_\partial$ to K_κ, and on through κ_∂ towards I_κ, without quite reaching I_κ again. This relation we call W_κ; the definition is



$$W_\kappa = K_\kappa |; U_\kappa \upharpoonright \kappa_\partial \mathbin{\updownarrow} U_\kappa \upharpoonright \kappa_\partial \quad \text{Df.}$$

Taking an arbitrary origin, a vector may be indicated by the point to which it carries the origin. Thus in the figure, I_κ is at the origin, K_κ is opposite the origin; the upper semi-circle, including both ends, is κ; not including the right-hand end, it is κ_∂; the lower semi-circle, including both ends, is $\mathrm{Cnv}``\kappa$; including $K_\kappa$ but not $I_\kappa$, it is $\mathrm{Cnv}``\kappa_\partial$; including I_κ but not K_κ, it is $K_\kappa | ``\kappa_\partial$. Then W_κ starts from I_κ, and proceeds through the lower semi-circle first, and afterwards through the upper semi-circle, stopping just short of I_κ.

If κ is cyclic, W_κ is a series. Under most circumstances, if $R \in \kappa$, we shall have

$$P W_\kappa Q \,.\supset.\, (P | R) W_\kappa (Q | R).$$

The investigation of the various cases in which this holds occupies a large part of $*371$.

In the remainder of this Section, our work becomes more full of ordinary arithmetic than it has been hitherto. We shall therefore, where cardinals are concerned, abandon the explicit notation we have hitherto employed, and substitute the ordinary notation. Thus we shall write $\mu + \nu$ in place of $\mu +_c \nu$, and $\mu\nu$ in place of $\mu \times_c \nu$. We shall, however, retain $\mu -_c \nu$ for subtraction, in order to avoid confusion with the sign of negation of a class.

We proceed next ($*372$) to consider what is in effect the class of vectors not greater than the νth part of a complete revolution (*e.g.* in the case of angles, not greater than $2\pi/\nu$). We define this by means of the relation W_κ. It will be seen from the figure that if R is a non-zero vector, we shall have $R^{\sigma+1} W_\kappa R^\sigma$, unless R^σ belongs to the lower semi-circle and $R^{\sigma+1}$ to the upper, in which case $R^\sigma W_\kappa R^{\sigma+1}$. The first time this happens is the first time that $R^{\sigma+1}$ becomes greater than one complete revolution. Hence if, for every number σ less than ν and not zero, $R^{\sigma+1} W_\kappa R^\sigma$, it follows that R^ν is not greater

than one complete revolution, and therefore R is not greater than the νth part of a complete revolution. The class of such relations we call ν_κ; thus we put

$$\nu_\kappa = (\kappa \cup \mathrm{Cnv}``\kappa) \cap \hat{R}(\sigma < \nu . \sigma \neq 0 . \supset_\sigma . R^{\sigma+1} W_\kappa R^\sigma) \quad \mathrm{Df.}$$

The main propositions to be proved in this subject are

$$P \epsilon \nu_\kappa . P W_\kappa Q . \supset . P^\nu W_\kappa Q^\nu$$

and (what is an immediate consequence)

$$P, Q \epsilon \nu_\kappa . \supset : P^\nu = Q^\nu . \equiv . P = Q.$$

This latter proposition is the foundation of the theory of principal ratios.

Another important property of ν_κ is

$$\breve{W}_\kappa``\nu_\kappa \subset \nu_\kappa,$$

so that ν_κ is an upper section of W_κ.

We proceed next (*373) to consider submultiples of identity, *i.e.* vectors R such that $R^\nu = I_\kappa$, where ν is a cardinal. We assume here, and almost always henceforth, that κ is a submultipliable family. We first consider vectors which can be reached from I_κ by successive bisections. We know that $K_\kappa{}^2 = I_\kappa$; if $R^2 = K_\kappa$, then $R \neq K_\kappa$, because $K_\kappa{}^2 \neq K_\kappa$. Hence by continuing the same process we arrive at the existence of a vector Q such that

$$Q^{2^\nu} = I_\kappa : \rho < 2^\nu . \rho \neq 0 . \supset_\rho . Q^\rho \neq I_\kappa.$$

Hence we easily arrive at the result that, if ν is any inductive cardinal, there is a non-zero vector whose νth power is I_κ. (This does not follow from $\kappa \epsilon FM\,\mathrm{subm}$ alone, because $I_\kappa{}^\nu = I_\kappa$, so that from the definition of $FM\,\mathrm{subm}$ we cannot know that there is any vector except I_κ whose νth power is I_κ.) Thence we prove that there are non-zero vectors whose νth power is I_κ, and which are such that no earlier power is I_κ, *i.e.* we prove

$$(\exists R) : R \epsilon \kappa_\partial . R^\nu = I_\kappa : \sigma < \nu . \sigma \neq 0 . \supset_\sigma . R^\sigma \neq I_\kappa.$$

The class of such vectors we call (I_κ, ν). If R is such a vector, the number of different vectors which are powers of R is ν. Hence the powers of R have a maximum in the order W_κ; since W_κ proceeds from greater to smaller vectors, this will be the smallest vector, other than I_κ, which is a power of R. Concerning this vector, we show that it is a member of ν_κ, *i.e.* it is such that, if $\sigma < \nu . \sigma \neq 0$, $R^{\sigma+1} W_\kappa R^\sigma$. Finally we prove that there is only one member of ν_κ whose νth power is I_κ. This will be what we may call the "principal" νth submultiple of I_κ; in the case of angles, it will be the angle $2\pi/\nu$. It will be observed that $2\pi\mu/\nu$ always has identity for its νth power, and has no lower power equal to identity if μ is prime to ν. Thus the uniqueness of the "principal" νth submultiple depends upon the fact that it is a member of ν_κ, so that, by what has been proved in the previous number, no other member of ν_κ has the same νth power.

We next, in a short number (*374), extend the last of the above results to any vector, proving that, if R is any member of $\kappa \cup \text{Cnv}``\kappa$, there is a unique member of ν_κ whose νth power is R. We may call this the "principal" νth submultiple of R. We prove also in this number that, if S is the principal νth submultiple of I_κ, ν_κ consists of all vectors not earlier than S in the order W_κ, *i.e.* of all vectors not greater than S.

Finally (*375) we define "principal ratios" and show that they are one-one and mutually exclusive. We denote the "principal ratio" corresponding to μ/ν by "$(\mu/\nu)_\kappa$." This is defined as the relation holding between R and S when the principal μth submultiple of R is identical with the principal νth submultiple of S; that is, we put

$$(\mu/\nu)_\kappa = \hat{R}\hat{S}\{(\exists T) . T \in \mu_\kappa \cap \nu_\kappa . R = T^\mu . S = T^\nu\} \quad \text{Df.}$$

It is obvious that $(\mu/\nu)_\kappa \subset (\mu/\nu) \upharpoonright \kappa_\iota$; and there is no difficulty in showing that principal ratios are one-one and mutually exclusive.

We have not thought it necessary to carry the development of this subject any farther, since, from this point onwards, everything proceeds as in the case of open families. We have given proofs rather shortly in this Section, particularly in the case of purely arithmetical lemmas, of which the proofs are perfectly straightforward, but tedious if written out at length.

$*370$. ELEMENTARY PROPERTIES OF CYCLIC FAMILIES.

Summary of $*370$.

In this number, after the definition of cyclic families already cited, we proceed first to prove that only one non-zero vector is equal to its converse ($*370{\cdot}23$). This one we define as K_κ. Next we prove that, if R is a non-zero vector other than K_κ, $R \mid K_\kappa$ is the converse of a non-zero vector, and $\breve{R} \mid K_\kappa$ is a non-zero vector ($*370{\cdot}31{\cdot}311$), whence it follows that

$$\text{D}`R = \text{ꓷ}`R = s`\text{ꓷ}``\kappa \quad (*370{\cdot}32),$$

whence further we obtain

$$\text{D}``\kappa = \text{ꓷ}``\kappa \,.\, \kappa \in FM \,\text{connex} \quad (*370{\cdot}33).$$

Hence further, since by definition $\kappa_\partial \rceil U_\kappa$ is transitive, it follows that $\kappa_\partial \rceil U_\kappa$ is a series ($*370{\cdot}37$). The remaining propositions ($*370{\cdot}4$—$\cdot44$) are concerned with the relations of the two semi-circles κ_∂ and $K_\kappa \mid ``\kappa_\partial$ (cf. figure, p. 459). We have

$$\text{Cnv}``\kappa = K_\kappa \mid ``\kappa \qquad (*370{\cdot}4),$$

$$\kappa \cap \text{Cnv}``\kappa = \iota`I_\kappa \cup \iota`K_\kappa \qquad (*370{\cdot}42),$$

$$K_\kappa \mid ``\kappa_\partial = \text{Cnv}``\kappa - \iota`K_\kappa \qquad (*370{\cdot}43),$$

and

$$\kappa_\partial \cap K_\kappa \mid ``\kappa_\partial = \Lambda \qquad (*370{\cdot}44).$$

Summary of *371.

In this number, we begin by defining the relation W_κ, which takes the place, for cyclic families, of the relation V_κ defined in *336. The definition is

***371·01.** $W_\kappa = K_\kappa \mid ; U_\kappa \upharpoonright \kappa_\partial \ddagger U_\kappa \upharpoonright \kappa_\partial$ Df

Then if κ is a cyclic family, W_κ is a series (*371·12), and its field is $\kappa \cup \mathrm{Cnv}``\kappa$ (*371·14), which $= \kappa_\iota$ since κ has connexity. It will be observed that V_κ is not a series if κ is a cyclic family; we have *e.g.* $I_\kappa V_\kappa K_\kappa \,.\, K_\kappa V_\kappa I_\kappa$. The above relation W_κ is constructed so as to make a barrier at I_κ, thereby preventing the relation W_κ from being cyclic.

If P, Q are both members of κ_∂ or both members of $K_\kappa \mid ``\kappa_\partial$,

$$P W_\kappa Q \,.\equiv.\, (\exists T) \,.\, T \in \kappa_\partial \,.\, P = Q \mid T \quad (*371·15·151).$$

Most of the properties of W_κ depend upon the fact that $\kappa_\partial \upharpoonleft U_\kappa$ is transitive, in virtue of the definition of cyclic families. If κ is any connected family, we have

$$\kappa_\partial \upharpoonleft U_\kappa \in \mathrm{trans} \,.\equiv:\, P, Q, Q \mid R, P \mid Q \mid R \in \kappa_\partial \,.\, R \in \kappa \,.\supset_{P,Q,R} .\, P \mid Q \in \kappa_\partial \quad (*371·2).$$

This proposition is required for most of the subsequent proofs in this number. It leads at once to

***371·21.** $\vdash : \kappa \in FM\,\mathrm{cycl} \,.\, P, Q, Q \mid R, P \mid Q \mid R \in \kappa_\partial \,.\, R \in \kappa \,.\supset.\, P \mid Q \in \kappa_\partial$

Most of the propositions of this number are concerned with the circumstances under which we can infer $(P \mid R) W_\kappa (Q \mid R)$ from $P W_\kappa Q$. We have

***371·31.** $\vdash :. \kappa \in FM\,\mathrm{cycl} \,.\, R \in \kappa_\partial : P \in \kappa_\partial \,.\vee.\, P \mid R \sim\in \kappa_\partial :\supset:$

*372. INTEGRAL SECTIONS OF THE SERIES OF VECTORS.

Summary of *372.

The subject of this number is that section of $\breve{W}_\kappa$ which consists of vectors not greater than the νth part of the whole circumference of the cycle. This is defined by means of W_κ, as consisting of those vectors which (taking W_κ as "greater than") are such that $R^{\sigma+1}$ is greater than R^σ so long as $\sigma < \nu$. It will be seen that so long as R^ν and all earlier powers of R do not exceed I_κ, R satisfies this condition; but if $R^\sigma \epsilon K_\kappa | ``\kappa_\partial$, while $R^{\sigma+1} \epsilon \kappa_\partial$, we shall have $R^\sigma W_\kappa R^{\sigma+1}$. Thus our definition selects those vectors which, starting from any origin, do not, by ν repetitions, take us farther than once round the cycle. The definition is

***372·01.** $\nu_\kappa = (\kappa \cup \mathrm{Cnv}``\kappa) \cap \hat{R}(\sigma < \nu . \sigma \neq 0 . \supset_\sigma . R^{\sigma+1} W_\kappa R^\sigma)$ Df

We then have $1_\kappa = \kappa \cup \mathrm{Cnv}``\kappa$ (*372·11), $2_\kappa = \kappa_\partial$ (*372·13), $\mu \leqslant \nu . \supset . \nu_\kappa \subset \mu_\kappa$, *i.e.* ν_κ diminishes as ν increases (*372·15); $\nu > 1 . \supset . \nu_\kappa \subset \kappa_\partial$ (*372·16).

An alternative formula for ν_κ, sometimes more convenient than the one given in the definition, is (assuming $\nu > 1$)

$$\nu_\kappa = \kappa_\partial \cap \hat{P}(\mu < \nu . \mu \neq 0 . P^{\mu+1} \epsilon \kappa_\partial . \supset_\mu . P^\mu \epsilon \kappa_\partial) \quad (*372·17);$$

i.e. so long as $\mu < \nu$, either P^μ comes in the upper semi-circle, or $P^{\mu+1}$ comes in the lower semi-circle; that is to say, the step from P^μ to $P^{\mu+1}$ does not cross I_κ. For an even number (not zero), this leads to a simpler formula, namely

$$(2\nu)_\kappa = \kappa_\partial \cap \hat{P}(\mu \leqslant \nu . \mu \neq 0 . \supset_\mu . P^\mu \epsilon \kappa_\partial) \quad (*372·18).$$

We have next a set of propositions leading up to

***372·27.** $\vdash :. \kappa \epsilon FM \mathrm{cycl} . \nu \epsilon \mathrm{NC\,ind} - \iota`0 . P \epsilon \nu_\kappa . P W_\kappa Q . \supset :$

$$\mu \leqslant \nu . \mu \neq 0 . \supset . P^\mu W_\kappa Q^\mu$$

whence, since W_κ is a series, we obtain

***372·28.** $\vdash :. \kappa \epsilon FM \mathrm{cycl} . \nu \epsilon \mathrm{NC\,ind} - \iota`0 . P, Q \epsilon \nu_\kappa . \supset : P^\nu = Q^\nu . \equiv . P = Q$

It is largely owing to this proposition that ν_κ is important. In virtue of this proposition, there is in ν_κ at most one vector which is the νth submultiple of a given vector. We shall show later that, if κ is a submultipliable

cyclic family, there is at least one such vector; hence there is a unique vector in ν_κ which is the νth submultiple of a given vector. This does not hold in general for larger classes than ν_κ.

A specially useful case of the above proposition is obtained by putting $\nu = 2$, which gives, in virtue of *372·13,

***372·29.** $\vdash :. \kappa \in FM \text{cycl} . P, Q \in \kappa_\partial . \supset : P^2 = Q^2 . \equiv . P = Q$

The remaining propositions of this number are concerned in proving that ν_κ is an upper section of W_κ, *i.e.*

*373. SUBMULTIPLES OF IDENTITY.

Summary of *373.

The purpose of this number is to prove that, in a cyclic submultipliable family, there exists a unique vector which is a member of ν_κ and satisfies $R^\nu = I_\kappa$. This we call the "principal" νth submultiple of I_κ. It is the smallest vector (other than I_κ) which satisfies $R^\nu = I_\kappa$. The proof of its existence proceeds by several stages; the problem is analogous to that of the construction of a regular polygon. Suppose the cycle divided into ν equal parts. Then a vector which takes us from any one point of division to any other is a νth submultiple of identity. If ν is prime, every such vector will have every power less than the νth different from I_κ; but if ν has factors, say ρ and σ, if $R^\nu = I_\kappa$, $(R^\rho)^\sigma = I_\kappa$; thus R^ρ, which is one of the νth submultiples of identity, has a power less than the νth which is equal to I_κ. We define (I_κ, ν) as the class of those νth submultiples of I_κ which have no power less than the νth equal to I_κ; more generally, we put

***373·03.** $(S, \nu) = \hat{P}(P^\nu = S : \sigma < \nu . \sigma \neq 0 . \supset_\sigma . P^\sigma \neq S)$ Dft

We then have first to prove the existence of $\kappa_\partial \cap (I_\kappa, \nu)$ when κ is cyclic and submultipliable. For this purpose, we put

***373·01.** $M_{\nu\kappa} = \hat{Q}\hat{P}(Q \in \kappa_\partial . Q^\nu = P)$ Dft

I.e. $M_{\nu\kappa}$ is the relation of a νth submultiple of P to P, when the submultiple of P is a member of κ_∂. It is to be observed that although κ is submultipliable, we do not know to begin with that I_κ has submultiples which are members of κ_∂, except in the case of K_κ, which is half of I_κ. Owing to this, we proceed first by bisection, *i.e.* by means of the relation $M_{2\kappa}$. We prove that the process of bisection can be applied endlessly to any member of κ_∂, and always gives new terms (*373·14·13), hence it gives a progression starting from any member of κ_∂ (*373·141), and therefore the existence of a cyclic submultipliable family implies the axiom of infinity (*373·142); also we prove that ν bisections starting from a member of κ_∂ give a member of $(2^{\nu+1})_\kappa$ (*373·15). Hence, taking K_κ as the member of κ_∂ to be bisected, we arrive at

$$\mu = 2^{\nu+1} . \supset . \exists ! \kappa_\partial \cap (I_\kappa, \mu) \quad (*373·17).$$

In order to extend this result to numbers not of the form $2^{\nu+1}$, we have

first to prove that there are μth submultiples of identity. This we prove first for numbers of the form $2^\nu + 1$, then for $(2\sigma+1)2^\nu+1$, and then for 2σ (*373·21·22·23); hence it holds generally, *i.e.* we have

***373·25.** $\vdash : \kappa \epsilon FM \text{ cycl subm} . \mu \epsilon \text{NC ind} - \iota`0 - \iota`1 . \supset . (\exists Q) . Q \epsilon \kappa_\partial . Q^\mu = I_\kappa$

Next, we prove that, if $R \epsilon \kappa_\partial$ and $R^\mu = R^\nu = I_\kappa$, then μ, ν have some common factor ρ such that $R \epsilon (I_\kappa, \rho)$, *i.e.* such that R^ρ is the earliest power of R which is I_κ (*373·3). Hence if μ is prime, and $R^\mu = I_\kappa$, it follows that no earlier power of R is I_κ, *i.e.* $R \epsilon (I_\kappa, \mu)$ (*373·32), and that, if $R \epsilon (I_\kappa, \rho)$ and $R^\mu = I_\kappa$, then μ is a multiple of ρ (*373·33).

We now make a fresh start with the general relation $M_{\nu\kappa}$. Owing to *373·25, we know that $I_\kappa \epsilon \text{G}`M_{\nu\kappa}$. Also since $\kappa$ is submultipliable, $\kappa_\partial \subset \text{G}`M_{\nu\kappa}$. Hence if α is any inductive cardinal, $I_\kappa \epsilon \text{G}`M_{\nu\kappa}{}^\alpha$ (*373·404). Also it is easy to show that if ν is a prime, and $QM_{\nu\kappa}{}^\alpha I_\kappa$, Q^{ν^α} is the first power of Q which is I_κ. Hence when ν is prime, $\kappa_\partial \cap (I_\kappa, \nu^\alpha)$ exists (*373·43). In order to extend this result to numbers which are not powers of primes, we prove

***373·45.** $\vdash : \kappa \epsilon FM \text{ cycl} . \rho \text{ Prm } \sigma . R \epsilon (I_\kappa, \rho) . S \epsilon (I_\kappa, \sigma) . \supset . \breve{R} | S \epsilon (I_\kappa, \rho\sigma)$

Hence by the help of a little elementary arithmetic we arrive at

***373·46.** $\vdash : \kappa \epsilon FM \text{ cycl subm} . \rho \epsilon \text{NC ind} - \iota`0 - \iota`1 . \supset . \exists ! \kappa_\partial \cap (I_\kappa, \rho)$

Having now proved that there are νth submultiples of I_κ which have no power short of the νth equal to I_κ, we have still to show that there is one among them which is a member of ν_κ. For this purpose, we take any one of them and consider its powers. It is obvious that it has only ν different powers (*373·5), since after reaching I_κ the previous values repeat themselves. It is this fact which makes it easier to deal with submultiples of I_κ than with submultiples of other vectors.

Now let R be any νth submultiple of identity, and assume that S, T are powers of R, but T is not a power of S, and $TW_\kappa S$. Then $\breve{S} | T$ is a power of R but not of S, and $TW_\kappa (\breve{S} | T)$ (*373·53). Hence T is not the maximum, in the series W_κ, of the class $\text{Pot}`R - \text{Pot}`S$. Hence by transposition, if T is the maximum of $\text{Pot}`R - \text{Pot}`S$, we must have $SW_\kappa T$. Now since $\text{Pot}`R$ is a finite class, $\text{Pot}`R - \text{Pot}`S$ must have a maximum if it exists; but since $S$ has the relation $W_\kappa$ to this maximum, $S$ is not the maximum of $\text{Pot}`R$. Hence by transposition, if S is the maximum of $\text{Pot}`R$, $\text{Pot}`R - \text{Pot}`S$ is null, and therefore $\text{Pot}`R = \text{Pot}`S$ (*373·54). Hence it follows easily that, if $R \epsilon \kappa_\partial \cap (I_\kappa, \nu)$, the maximum of the powers of R is a member of $\kappa_\partial \cap (I_\kappa, \nu)$ (*373·55), and further that it is a member of ν_κ (*373·56). Since we have already proved (*373·46) the existence of $\kappa_\partial \cap (I_\kappa, \nu)$, we thus have

***373·6.** $\vdash : \kappa \epsilon FM \text{ cycl subm} . \nu \epsilon \text{NC ind} - \iota`0 . \supset . \exists ! \nu_\kappa \cap \hat{S}(S^\nu = I_\kappa)$

The uniqueness of $\nu_\kappa \cap \hat{S}(S^\nu = I_\kappa)$ follows from $*372\cdot28$, and thus the principal νth submultiple of I_κ exists. Hence also it immediately follows that the other νth submultiples of I_κ are powers of the principal νth submultiple, and that the total number of νth submultiples is ν ($*373\cdot63\cdot64$).

$*374$. PRINCIPAL SUBMULTIPLES.

Summary of $*374$.

In this number we prove for any vector what was proved for I_κ in $*373$, namely that, if ν is any inductive cardinal not zero, and R is any vector, there is just one member of ν_κ whose νth power is R. This one we call the "principal" νth submultiple of R. The proof of its existence is as follows.

Assume R is a non-zero vector, and Q is a νth submultiple of R. (Q exists provided we assume that κ is submultipliable.) Let T be the principal νth submultiple of I_κ, whose existence has been proved at the end of $*373$. We wish to prove that there is a νth submultiple of R which is a member of ν_κ. By $*372{\cdot}33$, Q is a member of ν_κ if $TW_\kappa Q$. But if $QW_\kappa T$, then T must have a last power T^σ such that $QW_\kappa T^\sigma$, and for this value of σ we shall therefore have $T^{\sigma+1}W_\kappa Q$. (We cannot have $T^{\sigma+1} = Q$, because if Q were a power of T, we should have $Q^\nu = I_\kappa$, whereas by hypothesis $Q^\nu = R$.) Now if $T^{\sigma+1}W_\kappa Q \,.\, QW_\kappa T^\sigma$, the vector $\breve{T}^\sigma | Q$ must be less than T, *i.e.* we shall have $TW_\kappa(\breve{T}^\sigma | Q)$, and therefore $\breve{T}^\sigma | Q$ will be a member of ν_κ, by $*372{\cdot}33$. Moreover since $T^\nu = I_\kappa$, we have $(\breve{T}^\sigma | Q)^\nu = Q^\nu = R$ by hypothesis. Hence $\breve{T}^\sigma | Q$ is a νth submultiple of R and a member of ν_κ. In virtue of $*372{\cdot}28$, it is the only νth submultiple of R which is a member of ν_κ. Thus the existence of the principal νth submultiple of any vector is proved, assuming the family concerned to be cyclic and submultipliable.

We prove also in this number that ν_κ consists of all non-zero vectors not greater than the principal νth submultiple of I_κ, which is therefore the greatest member of ν_κ; that is, we have

$*374{\cdot}21$. $\vdash : \kappa \in FM \,\text{cycl subm} \,.\, \supset . \, \nu_\kappa = (\overleftarrow{W_\kappa})_*{}^\backprime(\imath R)(R \in \nu_\kappa \,.\, R^\nu = I_\kappa)$

$*374{\cdot}1$. $\vdash :. \kappa \in FM \,\text{cycl} \,.\, R, Q \in \kappa_\partial \,.\, Q^\nu = R \,.\, T \in \nu_\kappa \,.\, T^\nu = I_\kappa \,.\, \supset :$
$TW_\kappa Q \,.\, \supset . \, Q \in \nu_\kappa$ [$*372{\cdot}33$]

The above hypothesis is not all necessary for the conclusion, but is adopted because it gives the construction with which we shall be concerned.

Summary of *375.

In this number we define a relation $(\mu/\nu)_\kappa$, which is contained in $(\mu/\nu) \upharpoonleft \kappa_\iota$*, but has the advantage of being one-one, and of excluding $(\rho/\sigma)_\kappa$ unless $\mu/\nu = \rho/\sigma$. The relation $(\mu/\nu)_\kappa$ is defined as holding between R and S when the principal μth submultiple of R is identical with the principal νth submultiple of S, *i.e.* we put

***375·01.** $(\mu/\nu)_\kappa = \hat{R}\hat{S}\{(\exists T) . T \epsilon \mu_\kappa \cap \nu_\kappa . R = T^\mu . S = T^\nu\}$ Df

(Here $\mu_\kappa \cap \nu_\kappa = \mu_\kappa$ if $\mu \geqslant \nu$, and $= \nu_\kappa$ if $\nu \geqslant \mu$, by *372·15.)

The properties of $(\mu/\nu)_\kappa$ result from *374·2. We find that, except when $\mu = \nu = 0$ or $\xi = \eta = 0$,

$$\mu/\nu = \xi/\eta . \equiv . (\mu/\nu)_\kappa = (\xi/\eta)_\kappa \quad (*375·27).$$

If $\mu \leqslant \nu$, $\quad \mathrm{G}\text{‘}(\mu/\nu)_\kappa = \kappa \cup \mathrm{Cnv}\text{“}\kappa \quad$ (*375·141),

and $\quad \mathrm{D}\text{‘}(\mu/\nu)_\kappa = \overleftarrow{(W_\kappa)}_*\text{‘}(\mu/\nu)_\kappa\text{‘}I_\kappa \quad$ (*375·22).

The principal νth submultiple of S is $(1/\nu)_\kappa\text{‘}S$, and its μth power is $(\mu/\nu)_\kappa\text{‘}S$. Also we have

$$(1/\rho)_\kappa\text{‘}(1/\nu)_\kappa\text{‘}S = (1/\rho\nu)_\kappa\text{‘}S \quad (*375·15),$$

$$N \epsilon \nu_\kappa . \supset . (1/\rho)_\kappa\text{‘}N \epsilon (\rho\nu)_\kappa \quad (*375·16),$$

$$(\mu/\nu)_\kappa = (\mu/1)_\kappa \,|\, (1/\nu)_\kappa \quad (*375·2).$$

The propositions

$$(\mu/\nu)_\kappa \,|\, (\rho/\sigma)_\kappa = (\mu/\nu \times_s \rho/\sigma)_\kappa$$

and

$$\{(\mu/\nu)_\kappa\text{‘}R\} \,|\, \{(\rho/\sigma)_\kappa\text{‘}R\} = (\mu/\nu +_s \rho/\sigma)_\kappa\text{‘}R$$

do not hold without limitation. The former requires either

$$\mu \geqslant \nu . \vee . \sigma \geqslant \rho,$$

or that the converse domain should be limited to

$$\overleftarrow{(W_\kappa)}_*\text{‘}(\sigma/\rho)_\kappa\text{‘}I_\kappa,$$

i.e. to

$$\mathrm{D}\text{‘}(\sigma/\rho)_\kappa.$$

The latter requires either

$$\mu/\nu +_s \rho/\sigma <_r 1/1,$$

or

$$R \epsilon \mathrm{G}\text{‘}(\mu/\nu +_s \rho/\sigma)_\kappa.$$

---

* Except in the trivial case when $\mu = 0 . \nu = 0$. In this case, $(\mu/\nu) \upharpoonleft \kappa_\iota = \dot{\Lambda}$ but $(\mu/\nu)_\kappa = I_\kappa \dotplus I_\kappa$.

$$(\exists M) . M \in (\mu\rho)_\kappa \cap (\nu\sigma)_\kappa . P = M^{\mu\rho} . R = M^{\nu\sigma}.$$

The result follows by putting $Q = M^{\nu\rho}$.

Without the hypothesis $\mu \geqslant \nu . \vee . \sigma \geqslant \rho$, we have

$$(\mu\rho/\nu\sigma)_\kappa`R = (\mu/\nu)_\kappa`(\rho/\sigma)_\kappa`R,$$

if R is sufficiently small to ensure $(1/\nu\sigma)_\kappa`R \in (\nu\rho)_\kappa$, *i.e.* if

$$(\sigma/\rho)_\kappa`I_\kappa (W_\kappa)_* R,$$

i.e. if $\quad R \in \text{C}`(\rho/\sigma)_\kappa.$

***375·32.** $\vdash : \kappa \in FM \text{ cycl subm} . \mu/\nu +_s \rho/\sigma <_r 1/1 . R \in \kappa \cup \text{Cnv}``\kappa . \supset .$

$$\{(\mu/\nu)_\kappa`R\} \mid \{(\rho/\sigma)_\kappa`R\} = \{(\mu/\nu +_s \rho/\sigma)_\kappa`R\}$$

The proof follows immediately from the definitions.

The same result follows without the hypothesis $\mu/\nu +_s \rho/\sigma <_r 1/1$ provided R is sufficiently small to ensure

$$(1/\nu\sigma)_\kappa`R \in (\mu\rho + \nu\sigma)_\kappa,$$

i.e. $\quad R \in \text{C}`(\mu/\nu +_s \rho/\sigma)_\kappa.$
